Abstract

We evaluate the impacts of a randomized job-fair intervention in which jobseekers and employers can meet at low cost. The intervention generates few hires, but it lowers participants' expectations and causes both firms and workers to invest more in search as predicted by a theoretical model; this improves employment outcomes for less-educated jobseekers. Through a unique two-sided belief-elicitation survey, we confirm that firms and jobseekers have over-optimistic expectations about the market. This suggests that, beyond slowing down matching, search frictions have a second understudied cost: they entrench inaccurate beliefs, further distorting search strategies and labour-market outcomes.

1 A matching experiment

Matching frictions can prevent the efficient allocation of workers across firms, sectors and industries. The costs of this misallocation are especially large in developing countries, where profound economic transformations are causing rapid changes in the labour market (Bryan and Morten, 2019; Hsieh et al., 2019). However, there is little evidence on precise channels through which matching frictions make it difficult for firms to hire the right workers – or for workers to find the right firm.

In this paper, we provide new experimental evidence on the distortions generated by matching frictions in a fast-growing developing economy (Alfonsi et al., 2020; Abebe et al., 2021). We focus on the high costs that firms and workers have to bear to meet each other. These costs have well-known direct effects on the labour market: they slow down hiring and job-finding; and reduce the likelihood of good matches between workers and firms.¹ They can also have an understudied *indirect* effect. By reducing the exposure of firms to workers and of workers to firms, these costs can entrench inaccurate beliefs about the labour market, which, in turn, are likely to distort job-search and recruitment decisions, resulting in fewer and poorer matches. Our central contribution is to shed light on this second channel – through an experiment that provides a large one-time reduction in the cost of worker-firm meetings, and through a novel survey that provides corroborating evidence on workers and firms’ misperceptions about the labour market.

Our evidence comes from a country that is undergoing a rapid economic transformation: Ethiopia. Similar to many other fast-growing economies in Sub-Saharan Africa, Ethiopia is witnessing the expansion of non-traditional economic sectors, sustained workforce growth, and a strong build-up of secondary education. In this context, updating beliefs about the changing market fundamentals is particularly important. At the same time, acquiring information can be costly for workers and firms (Abebe et al., 2021).

We evaluate the impacts of reducing these costs by inviting to a job fair a sample of young jobseekers and of medium-to-large formal employers. At the fair, workers can meet several employers at a low marginal cost, and employers can easily talk to many potential young recruits. As a result, each side of the market has the opportunity to gather a large amount of information about the other side at low cost. Our experimental design is uniquely placed to fully explore matching frictions on both sides of the market.

¹ Eeckhout (2018) summarises some of the key theoretical literature. Additionally, recent structural work in both developed and developing countries consistently detects the presence of meaningful labour market search costs (DellaVigna et al., 2017; Van den Berg and van der Klaauw, 2019; Abebe et al., 2021).

First, we randomize participation within representative samples of both firms and unemployed jobseekers. Second, we collect data on the baseline search strategies of firms and jobseekers, including their labour-market expectations. Third, we gather rich information on their interactions at the fair, including meetings, interviews, and job-offers. Finally, we observe workers and firms' search strategies over the months following the fair. This allows us to test for immediate as well as delayed treatment effects on firms and workers.

We show that the fairs generate few immediate hires (one for every 12 firms that attended), but they lead to an increase in search effort among both firms and jobseekers. Specifically, after the fairs, firms increase the amount they spend on advertising positions and jobseekers increase the frequency of their visits to job boards. Moreover, some firms decrease their reservation quality for workers (shifting towards less-educated candidates) and jobseekers reduce their reservation wage. The effects on jobseekers are concentrated among those with secondary education only, and their employment prospects improve significantly as a result our intervention: permanent employment rates double and formal employment rates increase by almost 50 percent.

The pattern of offers and rejections at the job fair suggests that the intervention led firms and less educated jobseekers to correct their initially over-optimistic beliefs about the quality of available matches. Prior to the fairs, firms reported their intention to hire for high-quality professional position requiring tertiary education. Most offers, however, were extended to secondary graduates, for presumably lower-quality non-professional positions. In turn, secondary-educated jobseekers mostly rejected these offers. A natural hypothesis is that these results were driven by overoptimism about the quality of available tertiary graduates on part of firms, which was quickly corrected, and overoptimism about the likelihood of obtaining better job offers among secondary graduates.

To validate this hypothesis, we first provide evidence of over-optimism in our sample at baseline. Second, we provide evidence that the job fairs moderate this over-optimism on both sides of the market: treated firms expect to hire fewer workers, and treated workers set more realistic reservation wages and moderate the targets of their job search. For workers, these effects are again concentrated among those without tertiary education. Third, we use a theoretical model to show how an information shock can correct beliefs and spur higher search effort, in line with our results. Fourth, we consider two possible alternative explanations for our results, but fail to find empirical support for them.

In the final part of the paper, we delve deeper into the sources of inaccurate beliefs that firms and jobseekers bring to the labor market. Specifically, we went back to the field and ran a unique survey administered to a new sample of firms and young jobseekers – each side

selected respectively during hiring and during job search. Since we simultaneously observe representative samples of both sides of the market, this survey enables us to contrast beliefs with actual data on the true distributions. Our aim was twofold. First, we wanted to corroborate our findings on over-optimism. Experiments are typically not suitable to indisputably establish over-optimism, since they rarely have access to representative samples of both workers and firms (and hence what appears to be a mismatched belief in the experimental data may be the result of selection into the experimental sample, and not a genuine misperception). Second, while the previous literature has mostly focused on individuals' forecasts of their own future outcomes, we wanted to explore the beliefs that individuals hold about the structural features of the labor market – e.g. wage or ability distributions. These beliefs are central to the matching process, but have received limited attention in the literature.

The additional belief-elicitation exercise shows clear evidence that firms and jobseekers hold incorrect beliefs about labor-market fundamentals. Firms overestimate the ability of jobseekers, an effect driven by overconfidence in the ability of the tertiary educated, while jobseekers underestimate how difficult it is to attain higher-paid professional jobs. These results show that misperceptions about labor market fundamentals can persist in equilibrium, and that firms too can hold systematically inaccurate beliefs. Crucially, these results corroborate the specific misperceptions that were exposed by the firm-jobseeker interaction at the job fairs: firms are particularly overoptimistic about the ability of tertiary-educated jobseekers; and secondary-educated jobseekers are overoptimistic about the likelihood of attaining high-pay professional employment. These additional evidence supports our main interpretation of the experimental findings.

Our paper contributes to a small but growing literature on matching frictions and erroneous beliefs in developing countries' labor markets.

First, in contrast to this literature (Banerjee and Sequeira, 2021; Bandiera et al., 2021; Chakravorty et al., 2021), we study both sides of the market, not just jobseekers and we are the first to provide evidence that the search strategies of *both* firms and jobseekers are based on incorrect beliefs. We find that both firms and jobseekers revise their search strategies in response to an intervention that allows each side of the market to acquire more information on the other side. This is a novel finding in a literature that has so far been silent on the search decisions of firms.² No study to date has shown that firms'

² Two recent papers have begun to fill this gap by highlighting the role of recruitment costs and uncertainty about candidate ability (Singh et al., 2022; Hensel et al., 2022). Consistent with their findings, several experiments have documented that skill certification can improve jobseekers' employment prospects (Abebe et al., 2021; Bassi and Nansamba, 2021; Carranza et al., 2021).

recruitment strategies respond to interventions that increase exposure to jobseekers.³ This finding is surprising, as firms are often assumed to have rational, accurate expectations. After all, firms have considerably more exposure to the labor market than jobseekers.⁴ It also suggests that the distortions generated by workers’ miscalibrated search strategies are unlikely to be offset by optimal search strategies set by firms. Matching frictions may thus be deeper than previously thought.

Second, we find that moderating optimism can boost search effort and – among the most misinformed subgroup– improve employment outcomes.⁵ In contrast, recent studies in South Africa and Uganda document interventions that reduce over-optimism, but also depress job search and job finding (Banerjee and Sequeira, 2021; Bandiera et al., 2021).⁶ Correcting over-optimism is a particularly attractive policy option in settings where it leads to *more* search effort and employment, given that there are positive social benefits from expanding young individuals’ labor market participation in low-income countries. Since our results indicate that, prior to our intervention, search intensity was incorrectly calibrated due to misinformation, they suggest that, in such context, improving labor market information can improve the efficiency of labor markets.

We also provide a theoretical model that can reconcile these findings, since it shows the conditions under which correcting over-optimism will boost or depress job search effort. We present an intuitive model of search with a deadline to show that, as in DellaVigna et al. (2017) and Marinescu and Skandalis (2020), search effort increases in the vicinity of the deadline while at the same time, the chosen target is decreased. We find empirical support for this prediction in our data, for both firms and jobseekers. The same framework can account for increased search effort just before the expiration of unemployment benefits (Krueger and Mueller, 2010; DellaVigna et al., 2021; Marinescu and Skandalis, 2020) or in recessions (Mukoyama et al., 2018).⁷

³ Our findings complement the results in Abebe et al. (2021), who show that firm managers make biased forecasts about the results a recruitment intervention, and of Caria and Falco (2021), who present lab-experimental evidence that small-firm managers are excessively concerned about worker trustworthiness.

⁴ The median firm in our study is 22 years old, has 90 (average 250) employees, and hires many workers each year. In contrast, many jobseekers in our sample have never had a job.

⁵ These findings are consistent with recent literature studying the relationship between optimism and job finding in rich economies (Spinnewijn, 2015; Krueger and Mueller, 2016; Mueller et al., 2021; van der Klaauw and Ziegler, 2021).

⁶ One possible reason for the difference in results is that, in Bandiera et al. (2021), jobseekers mostly update their beliefs about their individual characteristics, not about the market as a whole. Yet a fall in one’s perceived individual rank may be psychologically more demotivating for a jobseeker than a revision of their beliefs about the fundamentals of the market.

⁷ See, however, Mueller and Spinnewijn (2023) who find no evidence of variation in search effort over the course of an unemployment spell in Sweden.

Third, we expand our understanding of the inaccurate beliefs that jobseekers and firms bring to the labor market. This is important, as the drivers of over-optimism in labor markets are not well understood (Balleer et al., 2023). Are jobseekers and firms overconfident about their own prospects relative to those of their peers, or do they instead misunderstand the fundamental parameters of the labor market in which they operate? Our detailed follow-up survey shows that representative samples of both firms and workers hold inaccurate beliefs about the fundamentals of the labour market. As discussed above, such misperceptions have important consequences, as these beliefs are central to the choice of an effective search strategy. By contrast, models of search and matching typically assume that, while market participants may suffer from asymmetric information – e.g., they may be uncertain about the skills of a particular worker or the characteristics of a particular job – they have accurate information about the relevant distributions from which these variables are drawn (Rogerson et al., 2005; Terviö, 2009; Wright et al., 2021). In this paper, we show that firms and jobseekers make decisions on the basis of beliefs that are not centered on the true underlying distribution.

2 The study population

We work in a rapidly growing urban center in a low-income setting, where frictions are likely to be prevalent in the labor market. Addis Ababa, capital of Ethiopia, is a good choice because it combines these characteristics with the additional feature that, at the time of our study, the main avenue through which firms advertise openings is through job-vacancy boards located in the center of the city. While the purpose of these boards is to facilitate job search, they nonetheless entail sizeable transaction costs – especially for jobseekers, who must incur substantial transport costs to visit, and then need to spend considerable time visually scanning the boards to identify suitable openings.

Screening by firms is also challenging, given the limited information that can be extracted from the CVs of young labor market entrants (Abebe et al., 2021). Like many growing cities in the developing world, Addis Ababa has recently experienced a large increase in the number of available jobs, coupled with high in-migration flows. This makes it hard for firms and jobseekers to have accurate beliefs about the distribution of wages, employment opportunities, and workers’ abilities. All these features suggest that job fairs are a promising intervention in this context.

2.1 Surveying jobseekers

The job fair intervention reported in this paper draws on the same sampling frame as Abebe et al. (2021) and was partially run alongside that experiment.⁸ The study involves a representative sample of young educated jobseekers in Addis Ababa. To select our sample, we first define geographic clusters using enumeration areas from the Ethiopian Central Statistical Agency (CSA).⁹ Our sampling frame excludes clusters within 2.5 kilometres of the center of Addis Ababa and clusters outside the city boundaries. Clusters are selected at random from the sampling frame. To minimize potential spillover effects across clusters, we impose the condition that directly adjacent clusters cannot be selected together.

In each selected cluster, we used door-to-door sampling to construct a list of all individuals who: (i) are aged between 18 and 29 (inclusive); (ii) have completed high school; (iii) are available to start working in the next three months; and (iv) are not currently working in a permanent job or enrolled in full time education. We randomly sample individuals from this list to be included in the study. The lists include individuals with different levels of education. We over-sample individuals with post-secondary education to ensure that they are sufficiently represented in our sample.

All randomly selected individuals were contacted to establish their willingness to participate in the study and be interviewed. We completed baseline interviews with 4,388 eligible respondents. We attempted to contact individuals by phone for at least a month (three months on average) and dropped individuals who could not be reached after at least three attempts. We also dropped any individual who had found a permanent job at the time of baseline and had been in this job at least six weeks. Finally, we dropped individuals who had migrated away from Addis Ababa during the phone survey. In all we were left with 4,059 individuals included in our experimental study. Of these 1006 were invited to the jobs fairs. Another 2226 were involved in the experimental interventions discussed in Abebe et al. (2021), while 823 remain in the control group.

We collected data through both face-to-face and phone interviews. We completed baseline face-to-face interviews between May and July 2014 and endline interviews between June and August 2015. Information was collected on the socio-demographic characteristics of study participants, their education, work history, finances, and their expectations and attitudes. We also kept in touch with all study participants by phone throughout the duration of the study, at which time we administered a short questionnaire on job

⁸ Abebe et al. (2021) report two parallel field experiments: a transport subsidy to visit job boards, and a workshop intervention to help jobseekers to signal their cognitive and non-cognitive skills to employers.

⁹ CSA defines enumeration areas as small, non-overlapping geographical areas. In urban centers, these typically consist of 150 to 200 housing units.

search and employment.¹⁰

We have low attrition: 93.3% of baseline respondents were re-interviewed at endline. Few covariates predict attrition and we are unable to reject a joint F -test that a set of key covariates have no effect on attrition (see Appendix Table B.12 in the Online Appendix). However, we do find that the individuals invited to the job fairs are slightly more likely to respond to the endline survey. Yet, because attrition is low overall (8% in the control group and 5.6% in the treatment group), we are not concerned that this affects our main results. Our key findings are robust to bounding our estimates using the method of Lee (2009). Attrition in the phone survey is also low; for example, we were still able contact 90% of the respondents in the final month of the study.¹¹

2.2 Surveying firms

We surveyed 498 large firms in Addis Ababa. These firms were sampled so as to be representative of large employers in the city, stratified by sector. All major sectors in the economy are covered, including construction, manufacturing, banking and financial services, hotels and hospitality, and other professional services. To sample firms, we first compiled a list of the largest 2,178 firms in Addis Ababa. Since no firm census exists for Ethiopia, we rely on a variety of data sources, including lists of formal firms maintained by different government ministries. In all, we gathered data from more than eight different sources. For the manufacturing sector, we rely on a representative sample of large firms that took part in the Large and Medium Enterprise surveys conducted by the Central Statistics Agency (CSA). For other sectors we requested lists of the largest firms from the government agency in charge of that sector. Whenever information on firm size is available, we impose a minimum size cut-off of 40 workers.

We draw the firms in our sample using sector-level weights to reflect the number of employers in that sector in the city. We construct these weights using representative labour-force data.¹² The firms are, on average, large by Ethiopian and African standards. The mean number of employees per firm is 171.5. This masks considerable heterogeneity, particularly in the ‘Tours & Hospitality’ sector which is dominated by small hotels and

¹⁰ Franklin (2018) shows that high-frequency phone surveys of this type do not generate Hawthorne effects and do not affect jobseekers’ responses at endline.

¹¹ Appendix Figure B.1 shows the trajectory of monthly attrition rates over the course of the phone survey.

¹² Table B.9 in the Online Appendix shows the number of firms surveyed in our sample, divided into five main categories. Column (2) provides weighted percentages obtained by applying the inverse of the weights used to sample the firms. For instance we surveyed NGOs (“Education, Health, Aid”) relatively infrequently because of the large number of NGOs in the data.

restaurants; when this sector is excluded, average firm size is 326 workers. Detailed information on firms’ total employment is given in Table 1, excluding casual daily laborers. On average, firms report employing 34 casual laborers per day.

The firms in our sample are growing in size and looking to hire new workers. At baseline, the median number of workers that a firm expects to hire in the next 12 months amounts to 12% of its current workforce. The median rate of hiring is highest (16%) among service sector firms, which are also the most likely to come to the job fairs. The most common types of workers whom firms expect to hire are white-collar workers, usually requiring university degrees. For details, see Appendix Table B.7.

2.3 Evidence of mismatched expectations at baseline

Our baseline data shows clear evidence of mismatched expectations between workers and firms – particularly in the market for lower-educated jobseekers, i.e., those that only completed high school.¹³ On one side of the market, the reservation wages and future earning expectations of low-educated workers are significantly higher than what firms are prepared to pay. On the other side, firms appear overoptimistic about the prospect of filling positions with low-education workers.

Table 2 presents summary statistics on this mismatch. Panel A compares jobseekers’ reservation wages with current wages at the firms that were invited to the fair. We show that jobseekers with a high-school diploma and no experience report a median reservation wage of 1,300 Birr per month. This is significantly higher than the median salary of 855 Birr that firms report offering to high-school graduates with no work experience. In contrast, jobseekers with tertiary education have reservation wages that are well within the boundaries of what is available in the market: on average, firms report paying recruits with a university degree around 4,500 Birr per month, which is well above the median reservation wage of 2,500 Birr reported by university graduates without experience at the fairs. Indeed, only 10% of tertiary graduates in our sample have a reservation wage above the average wage paid for employees with their qualifications.

We also find a mismatch when we compare jobseekers’ expectations of future earnings at baseline with actual earnings at endline (Table 2, Panels B and C). At baseline, the median response to the question “what will the average wage for someone of your skills and education be in one year?” is 1500. By contrast, the median wage among low-educated

¹³ This may arise because tertiary education tempers these mismatched expectations. By attending classes, reading, and networking at tertiary institutions, young people gather important information about the labor market that individuals who only complete high school do not.

participants at endline is 1000. Similar mismatches exist over longer horizons: at baseline, the median expected wage in five years is 3,500. In our second endline (roughly five years after the intervention), median earnings are only 1800. The mismatch is largely driven by individuals without previous work experience (the vast majority of the sample), suggesting that lack of exposure to the labour market is driving these unrealistic wage expectations.

Finally, jobseekers are also overly optimistic about the number of job offers they will receive and the probability of having a job in the future. At baseline, the average expected number job offers over the next 4 months is 1.3. At endline, the actual average total number of offers received over the past 12 months is only 0.42. At baseline, 70% of high-school graduates say there is a “medium”, “high” or “very high” probability, (30% say “high” or “very high”) that they will find a job in the next 12 months. However, at endline only 50% have any job and only 6% have a permanent job (Table 2, Panel C).

On the firm side, wages offered are clearly below what workers are willing to work for, at least for low educated workers, suggesting that they may find it more difficult to hire than they expect. We find some evidence of hiring challenges among these firms. At endline, we find that firms in our control group have on average 2.1 unfilled vacancies open, while they hired only over 3.9 workers over the last year.¹⁴

3 Experimental design

3.1 Randomization to the job fair

We assign treatment of jobseekers to the job fairs by geographical cluster, after blocking on cluster characteristics (see Abebe et al. (2021) for further details). The sample is balanced across all treatment and control groups, and across a wide range of outcomes – including baseline outcomes that are not used in the stratified randomization procedure. We present extensive balance tests in Appendix Table B.3. For each baseline outcome of interest, we report the p -values for a test of the null hypothesis that we have balance between treatment and control groups. We cannot reject the null for any of variables that we study.

We assign firms to either a treatment group or a control group. Firms in the treatment group are invited to attend the job fairs; control firms are not. We use block-level randomization techniques suggested by Bruhn and McKenzie (2009). Firms are first partitioned into five main industries (see Appendix Table B.9). Within each industry, firms

¹⁴ See the control means in Table B.14.

are partitioned into blocks of four nearest neighbors on the basis of their Mahalanobis distance over a set of baseline variables.¹⁵ We then randomize the firms in each block into two groups of two firms: one firm is invited to the first day of the job fair; the second is invited to the second day (see below for details); and the other two are assigned to serve as controls. Given the relatively small size of the firm sample, we use a re-randomization approach to ensure balance on a set of baseline covariates listed in Table B.4.¹⁶

3.2 Implementation of the job fairs

We invited treated jobseekers and treated firms to attend two job fairs. The first fair took place on October 25 and 26, 2014. The second fair took place on February 14 and 15, 2015. We run two fairs to increase the chance that each jobseeker and firm is able to participate in at least one of them. The job fairs were held at the Addis Ababa University campus, a central and well-known location. To minimize congestion, each job fair lasted two days and a randomly selected half of the firms and jobseekers were invited to attend on each day. The firms that were invited to attend on Saturday 25 October were then invited to attend on Sunday 15 February; firms invited for Sunday 26 October were invited for Saturday 14 February. In contrast, jobseekers invited to attend on the Saturday of the first fair were also invited to attend on the Saturday of the second fair; jobseekers invited for the Sunday of the first fair were invited for the Sunday of the second fair. This ensures that, in each job fair, jobseekers are exposed to a different pool of firms, and that firms are exposed to a different pool of jobseekers.¹⁷

During each fair, jobseekers and firms are free to interact as they see fit. Each firm sets up a stall before the jobseekers arrive. These stalls are typically staffed by the firm’s HR team who bring with them printed material advertising the firm. In a typical interaction, a jobseeker approaches the stall of a firm and asks questions about the firm and its vacancies. The firm’s HR staff is then free to check his or her CV and to ask

¹⁵ The variables used for blocking are listed in Appendix Table B.10.

¹⁶ Following the recommendations of Bruhn and McKenzie (2009), we control for these covariates in our estimation, as well as for the baseline covariates used to construct the randomization blocks. Details of these variables and how they are defined are contained in our detailed pre-analysis plan. Simulations show that, with this sampling strategy, we have 78% power to detect a small treatment effect of 0.2 standard deviations at a significance level of 0.05%.

¹⁷ Weekend days are selected to maximize the opportunity for both firms and jobseekers to attend. In preliminary discussions with firms, we realized that most would be unable to take time off from daily activities to attend during the week, but they were interested in attending on a weekend. Similarly, many jobseekers in our sample work in casual jobs and are more likely to be unavailable during the week. Since many Ethiopians attend religious services on the weekend, we set a long enough time window for jobseekers to be able to attend.

about the jobseeker’s skills and work experience. If the jobseeker looks suitable for one of the firm’s vacancies, the firm invites her or him for a formal job interview a few days after the job fair.

To avoid self-selection out of the sampling frame, we do not restrict invitations to the fairs to currently unemployed jobseekers, or to firms that have open vacancies at the time of the fair. Of our initial sample of jobseekers, only about 8% had permanent jobs by the time of the first job fair, and thus most jobseekers were still searching for work. Similarly, most firms were hiring at the time that the job fairs were held. 89% hired at least one worker in the year of the study and, on average, firms hired four workers in the month after the job fairs and 52 workers in the year of the fairs.

In total, we invited 1,007 jobseekers and 248 firms to attend the fairs. Both jobseekers and firms were contacted by phone, were given some information about the nature of the fairs, and had the opportunity to ask questions. Among firms, 170 attend at least one job fair, which represents quite a successful take-up rate of 68.5%. Of the firms that do not attend the fairs, 12% say it is because they do not have an open vacancy at the time. The remaining firms tend to cite logistical issues or previous commitments. Only 13 firms respond that they would not find the job fair useful.¹⁸

Of the 1007 invited jobseekers, 606 attend at least one fair, a 60% take-up rate. The most common reason that jobseekers give for not attending the fairs is that they are busy during that particular weekend. This reason is given by 226 jobseekers in the first fair and 229 jobseekers in the second. Other reasons include not being able to take a new job (9 jobseekers at the first fair and 83 at the second) and finding the venue of the fair hard to reach (31 respondents for the first fair and 25 for the second).

Two baseline characteristics predict higher attendance by jobseekers: search effort at baseline; and whether the jobseeker uses a school certificate during job search. It follows that jobseekers who attend the fairs are, if anything, more active and organized in their job search. Those who attend are also more likely to have a university degree or diploma, but this is not statistically significant. Taken together, this evidence provides reassurance that results are not driven by negative selection of jobseekers coming to the fairs.

¹⁸ In Appendix Table B.11, we run a descriptive regression to explore correlates of firm attendance at job fairs.

3.3 Matching at the fairs

In order to increase match efficiency and avoid congestion at the fairs, we did two things to facilitate higher-quality matches between workers and firms.¹⁹

First, at the beginning of each fair, we give jobseekers a list of all the firms invited with basic information on each firm.²⁰ Second, we ask firms to list up to 10 jobseekers with whom they would like to talk during the job fair. After collecting the list of requested meetings from each firm, we post them on a board at the fair for jobseekers to see.²¹ Third, we create a list of 15 recommended meetings for each jobseeker with suitable firms. Of the 15 firms on the recommended list, 10 are selected using a Gale-Shapley Deferred Acceptance algorithm described below (Gale and Shapley, 1962); the other five are selected at random.²² Each firm similarly receives a personalized list showing the names of all the jobseekers who have been recommended to meet that firm.

To produce our lists of suggested meetings, we start by asking jobseekers and firms to state their preferences regarding potential matches, over a set of worker and firm characteristics. We then construct a synthetic ranking of all vacant positions for each jobseeker, and a similarly a synthetic ranking of all jobseekers for each firm. The rankings of jobseekers by firms are constructed using lexicographic preferences over a series of jobseeker and firm attributes.²³ For the jobseeker’s rankings of vacancies, we use a simple ranking over the advertised wage.²⁴ We then use a Gale-Shapley algorithm to match jobseekers and firms. Specifically, the algorithm generates a single set of matches; we then iterate the algorithm 10 times, requiring a different set of recommended matches each time.²⁵ This generates 10 recommended matches to which we add five random one.

Figure 1 illustrates the outcome of the matching algorithm. Each point represents

¹⁹ This matching service was offered to reduce the time wasted by jobseekers and firms seeing unsuitable matches. This was done to increase the effectiveness of our intervention and partly compensate for the fact that, compared to real-world fairs, ours could not count on more advanced technologies such as apps and websites through which candidates could screen firms and vice versa.

²⁰ In the second fair, we also give jobseekers the list of all vacancies.

²¹ Given the logistics of collecting lists of names from more than a hundred employers, the lists were posted a few hours after the beginning of the fair.

²² The order of presentation on each list is similarly randomized. We tell jobseekers that these are the firms they should talk to during the fair.

²³ The ranking of jobseekers is based on (i) whether the jobseeker held a previous occupation that matches that of the vacancy; (ii) the jobseeker’s educational qualification for the job; and (iii) the jobseeker’s years of wage employment. The rankings of jobseekers vary across firms.

²⁴ This means that, for the purposes of forming recommendations, all jobseekers synthetically rank vacancies in the same way.

²⁵ We implement this requirement by taking the matches recommended in iteration t and placing those matches at the bottom of the firms’ and jobseekers’ rankings in iterations $s > t$.

a stable match recommended by the algorithm. The figure shows which combinations of firm rankings and jobseeker rankings generated these recommended matches. The graph provides a visual illustration that the algorithm worked well – in the sense of generating matches between firms and jobseekers who are, on the basis of jobseeker skills and experience, reasonably suitable for each other. Note the substantial mass at the bottom-left of the graph; this mass shows that, for those firms paying higher wages, the algorithm recommends matches that provide a reasonable occupational fit. For example, for the top 100 firms in the jobseekers’ ranking, the median match is to a jobseeker with a firm ranking of just 14, that is, a jobseeker ranked quite high according to our synthetic firm preferences.

4 The effects of the fairs

In this section, we document the impacts of the job fairs on employment outcomes and search behaviour – both at the level of the jobseeker and at the level of the firm. We begin by presenting evidence on hiring that took place at the fairs and in their immediate aftermath. We then present impacts on employment and search outcomes at endline (six months after the second fair), as well as impacts on jobseekers’ and firms’ expectations. We also present evidence on the trajectories of impacts based on a high-frequency survey conducted between baseline and endline.

We measure employment outcomes through data on job interviews, offers, hiring, and employment in different types of jobs. To test for impacts on search behaviour, we estimate treatment effects on the search strategies used by firms and jobseekers at endline (e.g., amount spent on advertising vacancies, amount of time spent looking for jobs). It should be noted that impacts on search behaviour are more likely to be observed if a direct effect on hiring is absent or weak: if treated jobseekers find a job and firms fill their vacancies as a direct outcome of the fairs, they have little cause to revise their expectations and search strategy.²⁶ Finally, we test for impacts on jobseekers’ and firms’ expectations at endline by analysing the effect of the treatment on jobseekers’ reservation wages and on firms’ hiring expectations.

²⁶ The pre-analysis plan that we filed for this experiment can be found at <https://www.socialscisceregistry.org/trials/1495>. Most pre-specified outcome families are presented in the order in which they appear in the pre-analysis plan. Those that are not documented here in detail can be found in the Online Appendix.

4.1 Immediate impacts: Hiring at the job fairs

The fairs generated rich interactions between firms and jobseekers. 454 jobseekers (75% of those attending) interacted with at least one firm at the job fair, either through an informal interview or an in-depth discussion with a recruiter. This finding is particularly strong among participants who benefited from the matching algorithm treatment (as discussed below). In total, we record 2,191 contacts between firms and jobseekers.

The interactions at the fairs resulted in 105 formal job interviews conducted at participating firms in the immediate aftermath (the finding is based on a phone survey conducted immediately after each fair).²⁷ Further, these 105 interviews are concentrated on 67 jobseekers only, representing 11% of those attending the fairs. These interviews led to 76 offers (made in the immediate aftermath of the fairs) to a total of 45 jobseekers, which represents a healthy conversion rate of one offer for each 1.4 interviews (and compares favourably with the open-market rate of 1.9).

Most firms came to the fairs expecting to recruit for high-quality professional jobs, which had minimum education requirements of a tertiary degree. In a survey focused on the vacancies open before the fairs, firms reported that they expected a diploma or degree for 84% of professional jobs, compared to 23% for other occupations. However, they mostly made offers for different and (plausibly) lower-quality positions to individuals with only secondary education.²⁸ Surprisingly, a large majority (81%) of these offers were rejected. The offer rejection rate was particularly high among less-educated jobseekers: 85% for applicants with a high-school diploma compared with 71% for those with tertiary education. Only 33% of offer recipients with a high-school diploma accepted an offer. Overall, we find that the fairs had little immediate impact on hiring by treated firms (Appendix Table B.14 and B.15).

We view these findings as *prima facie* evidence of a belief mismatch. Specifically, we hypothesize that firms were disappointed with the quality of the tertiary-educated workers who attended the fairs and so did not make offers for professional jobs that required tertiary education. Instead, they tried to recruit for non-professional positions targeted towards secondary graduates. On the other hand, the secondary-educated jobseekers came to the fairs with the unrealistic expectation that they would receive formal and professional job offers. They were disappointed when they did not receive such offers, and rejected the lower quality job offers that were extended to them. The remainder of

²⁷ This implies a rather low conversion rate of 1 interview for each 20.9 contacts established at the fair (in the open market, we estimate that jobseekers get an interview every 3.5 applications made).

²⁸ 55 offers (72%) went to jobseekers with at most a high-school diploma, even though they represented a minority of the jobseekers attending.

this paper presents evidence that is consistent with this interpretation. In particular, we find corroborating evidence of these biases in beliefs in the representative survey we ran after the end of the experiment.

In Appendix A, we test whether the limited impacts of the fairs on hiring may be due to the market being too thin (too few high-quality matches available), or to problems of congestion and mis-coordination during the fairs. We have evidence against both hypotheses. First, we document that the firms attending the fairs had a large number of open vacancies at the time of the event and the occupational composition of those vacancies exhibits considerable overlap with the distribution of occupations desired by invited jobseekers. Second, using dyadic data on firm-worker interactions, we show that our stylized matching algorithm was useful in identifying matches that were deemed worth pursuing by market participants. Specifically, we show that our synthetic rankings strongly predict both requested meetings and actual meetings. The fairs thus appear to have reached their objective of facilitating meetings between jobseekers and the firms that suited them best. This reassures us that our setup managed to minimise wasteful interactions and potential congestion.

4.2 Endline impacts on optimism, search, and employment

In this section, we examine the impacts of the intervention at endline (six months after the second fair). We report impacts on firms and workers separately. For the latter, we also leverage a high-frequency survey to study the trajectories of impacts in the months following the job fairs. Overall, we find clear evidence that both firms and jobseekers increase their search effort as a result of being invited to the fairs, and this leads to changes in employment outcomes that are particularly evident for the group of jobseekers that revised their search strategies the most (less-educated workers).

4.2.1 Impacts on firms' search strategies and hiring outcomes

First, we study the impact of the intervention on the search and hiring outcomes of firms measured at endline. To this end, we use an ITT approach with an ANCOVA specification. Following current practice, covariates used for balancing the randomization are included as controls. For each outcome of interest, we estimate regressions of the form:

$$y_i = \beta_0 + \beta_1 \cdot \mathbf{fairs}_i + \alpha \cdot y_{i,pre} + \boldsymbol{\delta} \cdot \mathbf{x}_{i0} + \mu_i, \quad (1)$$

with robust standard errors. Variable $y_{ic,pre}$ is the dependent variable measured at baseline and \mathbf{x}_{i0} includes the randomization variables listed in Table B.4. In the tables, we show each regression as a row and we report the estimated ITT ($\hat{\beta}_1$), the mean of the control group, and the number of observations. We report both p -values and False Discovery Rate q -values, the latter being calculated across the family of outcomes (Benjamini et al., 2006). Throughout this paper, we report the average treatment effect of the job fairs. As outlined in the pre-analysis plan, our study was designed to enable us to estimate separately an effect of the fairs both with and without additional information revelation about workers’ abilities. Since we found no direct effect of the fairs on hiring for either treatment arm, and the experimental information revelation was designed specifically to improve direct hiring at the fairs, we took the decision to pool the treatment arms. This improves the precision of our null estimates of the direct effects of the fairs.

Our first finding is that, as a result of the job fairs, firms invested more in worker search and recruitment. Our regression estimates, presented in Table 3, show that treated firms are six percentage points more likely to advertise new vacancies in the last 12 months, relative to a control mean of about 79%. They are also 12 percentage points more likely to advertise for professional positions, relative to a control mean of 60%.²⁹ Firms are also almost 10 percentage points more likely to advertise their vacancies on the job boards, relative to a control mean of 33 percent. All three effects are statistically significant after controlling for multiple hypothesis testing. This suggests that the intervention leads both firms and jobseekers to search more intensely through the main channels available to them at the time of the study.³⁰

Our second finding is that firms reorient their hiring away from highly educated workers, in particular for professional positions. In other words, they lower the reservation quality of their hires. Among firms that hire above the median number of professional workers – a pre-specified dimension of heterogeneity – we find that, apart from investing more in recruitment, the fairs also: (i) significantly reduce the proportion of professional workers with degrees by about 7 percentage points (relative to a control mean of 72 percent); (ii) reduce hiring by an average of 17 workers (over a control mean of 62 workers);

²⁹ Throughout the analysis, we distinguish between professional workers and non-professional workers. ‘Professional workers’ refers to traditional notions of ‘white-collar employees’: typically those with some degree or diploma working in relatively highly skilled positions. For manufacturing firms, ‘non-professional workers’ refers mostly to production workers; for service-based firms, these include mostly workers dedicated to client services (tellers, waiters, receptionists, *etc*).

³⁰ We do not find significant heterogeneity in these impacts. However, effects on recruitment appear to be larger among firms that did not hire many young people at baseline (Table B.22). This result is consistent with a learning story, as those firms likely have noisier and more inaccurate priors about young people in the labour market.

and (iii) reduce overall firm size.³¹ These results are consistent with the fact that firms at the job fairs did not extend interviews to workers with degrees (as discussed above). Importantly, they are also consistent with the finding – discussed below – that firms in this labour market have overly optimistic beliefs about the ability premium of highly educated workers. The fairs lowered their expectations. Another piece of evidence consistent with this conclusion is that, for the twelve months following endline, treated firms report lower expectations of hiring workers for occupations that require a higher educational level (Table 6).

We see these two results as consistent with a narrative in which firms realize that the quality of high-educated workers is lower than they thought. Hence they understand that it is going to be more challenging to find workers at the desired level of quality for the professional positions they need to fill. They respond by searching harder (advertising for professional positions), while also lowering their quality standards and hiring a larger share of less educated workers. The model we present in Section 5 formalises this idea.

Finally, the changes in firms’ recruitment strategies have only small effects on aggregate hiring outcomes at endline. We find a small but significant increase in unfilled vacancies over the 12 month period from baseline to endline (in Panel A of Table B.13). We find no impact on the time taken to fill open positions or on firms’ reported costs of recruitment. We find no significant impact on the number of people hired in the last 12 months, the hiring of job candidates with a degree, or hiring on a permanent contract (Panel B of Table B.13).³² This is perhaps not surprising, given that our sample is composed of large firms that hire on average 56 new workers per year. In these firms, changes in recruitment practices may take a longer time to affect the overall composition of the workforce.

4.2.2 Jobseekers’ search strategies and employment outcomes

Next, we examine the effect of the treatment on jobseekers’ search and employment outcomes. The specification we estimate is the same as equation 1, but we now focus on jobseekers rather than firms. To account for the fact that jobseekers were randomized to treatment according to their enumeration area of residence, standard errors are clustered by enumeration area. We report both conventional p -values and False Discovery Rate q -values.

³¹ Results (i) and (ii) are presented in Table B.26 in the Appendix, result (iii) is shown in Table B.25.

³² Similarly, we find no impact on the firms’ overall workforce composition (Appendix Table B.16), overall turnover and employee growth (Appendix Table B.17), and general HR practices (Appendix Table B.18).

We find that the the treatment increases jobseekers’ search effort. This is reflected in a higher number of visits to job boards at endline as shown in Panel A of Table 4: treated jobseekers report roughly three more visits to the job boards, relative to a control mean of 15. We can plot the trajectory of the effects on search over time, using high-frequency phone call survey conducted between baseline and endline. Figure 2 shows that the probability that a jobseeker visits the boards goes up by about 8.3 percentage points (26 percent) in six weeks following the first job fair.³³ Since the job boards are the main source of information on vacancies, this represents a sizeable increase in their effort to search for employment, equivalent to an ITT 0.15 standard deviation increase in the number of visits to the boards. Since only 60% of invited jobseekers attend the job fairs, the LATE equivalent is a sizeable 0.25 SD treatment effect.³⁴

Turning to the impacts of the fairs on the employment outcomes of jobseekers, we find that the effects are concentrated among the least educated ones, who experience a large increase in employment quality due to the intervention.³⁵ In Panel B of Table 4 we disaggregate treatment effects by whether or not the respondent has more than secondary education. Among the less educated jobseekers, we document an increase of 6 percentage points in the probability of having a permanent job relative to a control mean of just 6 percent at endline – i.e., a doubling of the probability of permanent employment. We similarly find an increase in the probability of having a formal job by 5 percentage points relative to a control mean of about 11 percent – i.e., a 45% improvement.³⁶ It is important to note that less educated workers are also the ones that experience the most significant changes in the search strategies, driving the average impacts discussed above (i.e., higher

³³ Specifically, we estimate this difference in probabilities using a Linear Probability Model in an ANCOVA specification, in which we regress job search on treatment, baseline search status and a sector of baseline balancing variables. We cluster at the level of individual jobseekers, and show both point estimates and 90% confidence intervals; we do this both by regressing on fortnight dummies, and by imposing a quadratic shape.

³⁴ Job-search is a self-reported variable and hence may be subject to experimenter demand effects (EDEs). There are at least three reasons why we do not believe that EDEs are likely to distort participants’ answers in our experiment. First, we do not observe impacts on job search when we offer a job application workshop — an intervention designed to optimize job search and hence more likely to generate EDEs on reported job search — to the same population in a separate paper (?). Second, the impact heterogeneity by education is not easily reconciled with EDEs, as it is not clear why EDEs would be stronger for less educated jobseekers. Third, a potential source of EDEs is the fact that individuals were called repeatedly over the phone. However, this was kept constant across experimental groups.

³⁵ The focus on job quality rather than sheer employment is justified by the fact that low-quality jobs are relatively easy to attain and the employment rate may not be the relevant margin of impact in this context, as discussed in Abebe et al. (2021).

³⁶ In the bottom row of Table 4 we report p -values for the null hypothesis that treatment effects are equal across educational categories. The null is rejected for wage mismatch and having a permanent job, and it is close to being rejected ($p < 0.12$) for visiting job board and having a formal job.

search effort and lower reservation wages).³⁷ This is consistent with the hypothesis that changing search strategies in light of the information acquired at the fairs leads to better labour-market outcomes for less-educated jobseekers.³⁸ Recall also it was less educated workers who exhibited unrealistic reservation wages and employment prospects before the fairs, as shown in Table 2.

4.2.3 Experimental evidence on expectations

We find several key impacts that are consistent with the idea that the fairs affected search behaviour and eventually employment by inducing a change in expectations. For jobseekers, Table 5 (Panel A, column 1) shows that treatment results in a significant 7 percent reduction in the endline reservation wage, and is equivalent to a 0.1 standard deviation decrease for the ITT, and a corresponding 0.17 SD decrease for the LATE.

To test whether treatment brings reservation wages more in line with market conditions, we construct a ‘wage mismatch’ variable equal to the percentage by which a jobseeker’s reported reservation wage differs from the average wage earned by a worker with the jobseeker’s skill and education. We present treatment effects on this variable in column 2 (Panel A). We find that treatment reduces the wage mismatch by a significant 4 percent.

In Panel B of Table 5, we then split these impacts between respondents with only a high-school diploma and those with post-secondary education. We find that each of the impacts is driven by the less educated respondents – precisely the group showed, in section 2.3, to have a stark mismatch of expectations. Again, this is consistent with the hypothesis that the fairs induced overoptimistic jobseekers to reduce their expectations, which in turn caused them to increase their search effort.

For firms, we measured expectations of the *number* of workers that they would hire in the next year. The results are shown in Table 6, and are also consistent with the hypothesis that the job fairs had an effect on employers’ expectations: specifically, we find that firms that attended the fair expect to hire approximately 30% fewer workers over the next 12 months, at the time of the endline survey.³⁹

³⁷ They reduce their reservation wages by 9 percent as a result of treatment, closing the mismatch between reservation wages and market wages by 7 percent. They increase their visit to the job boards by 4.2 percent, relative to a control mean of 11 visits.

³⁸ Additional treatment effects on employment outcomes, job amenities, and job search at endline are presented in Appendix Tables 4, B.5, and B.6.

³⁹ Of course, for firms, it is intrinsically harder to find direct evidence of changes in overall hiring expectations. For many vacancies, new hires need to be found, and firms may have subtly downgraded their expectations of the quality of the candidates that they would find for each position.

5 Mechanisms

The results in section 4 suggest that the experience of attending the fairs and not finding a suitable match persuaded each side of the market to (i) moderate their optimistic beliefs, and (ii) increase their search effort. We also find some evidence – among specific subgroups – that the fairs had moderate effects on reservation quality.⁴⁰ In this section, we provide a theoretical framework and some empirical evidence to shed light on how these margins of impact relate to one another. Our preferred interpretation is that the fairs caused an initial change in participants’ beliefs (and hence in reservation quality), which in turn led them to increase search effort. These two effects on search effort and reservation quality then caused the downstream impacts on employment and recruitment outcomes. We show this causal chain in Figure 3 below. We then proceed in two steps. First, we illustrate how these effects fit together in a simple search model. Second, we provide empirical evidence on the key mediating role of beliefs and additional evidence to rule out alternative explanations of these findings.

5.1 A dynamic model of search under distorted beliefs

We now present a stylised theoretical framework that helps us to interpret the results outlined above, and offers an explanation for the observed changes in search behaviour after the fairs. (We summarise the model here, and present a detailed discussion in Online Appendix A.) The model formalises the notion that firms and jobseekers held beliefs that made them overly optimistic about the possibility of finding a good match, given their existing investments in search. The model demonstrates how an information intervention that *reduces* over-optimistic beliefs can cause an *increase* in search effort – in contrast to the canonical predictions of stationary search models (see, for example, [McCall, 1970](#)).

To achieve this, we consider a firm that aims to fill a single vacancy and incurs a loss if it is left unfilled. This captures the intuitive idea that, if the position is left unfilled, the organization of production is negatively affected and firm productivity is lower. The model also incorporates important features observed among surveyed firms – notably, that firms (i) often have a specific notion of a minimum appointable standard when advertising a position, and (ii) seldom hire quickly for an advertised position. At the end of this subsection, we discuss how the same framework usefully captures the search problem of a jobseeker who has limited time and resources to fund their job search, and a reservation

⁴⁰ Firms shift hiring away from high-educated workers and workers are less likely to be targeting permanent jobs, and lower reservation wages.

utility level that puts a lower bound on their reservation wage.

The model firm searches in discrete time (with discount factor $\beta < 1$). In each period that the vacancy remains unfilled, the firm suffers a direct reduction in profit of $\kappa > 0$; this could reflect, for example, the cost of being unable to proceed with a project for want of filling the vacancy. In each period that the vacancy remains unfilled, the firm may spend $s \geq 0$ to generate k matches with prospective employees, such that $k | s \sim \text{Poisson}(s)$. The quality of any given match $x > 0$ is drawn from some distribution $F_X(x; \mu)$, where the mean μ represents the firm's belief about the quality of available applicants. We denote by y the quality of the best match realised in a given period (where $y \equiv 0$ if there are no matches).⁴¹

Having observed y , the firm decides whether to hire. The firm optimally does this using a cutoff rule, comparing y to some reservation match quality \bar{x} ; thus, the firm hires if $y \geq \bar{x}$ and otherwise prefers to leave the position open. We impose that the firm has some minimum match quality z , implied by the technical requirements of the position; this operates as a lower bound on the firm's choice of \bar{x} . For example, there is a minimum set of technical skills that a crane driver must reach before she can be employed – irrespective of how costly the firm finds it to leave the position vacant. The exogenous minimum candidate quality ($z \gg 0$) may also reflect organisational constraints by which firms may face internal morale consequences by hiring underqualified candidates at a posted wage (see, for example, [Breza et al., 2018](#)).

The value of meeting a best applicant with quality $y \geq \bar{x}$ is simply $V(y) = y/(1 - \beta)$. Note that the firm is indifferent between all values of $y \in [0, \bar{x}]$; therefore, the value to the firm of leaving the position unfilled is defined recursively as:⁴²

$$V(0) = \max_{s \geq 0; \bar{x} \geq z} -\kappa - \alpha s + \beta \cdot \mathbb{E}[V(y | s; \bar{x}, \mu)], \quad (2)$$

where

$$\mathbb{E}[V(y | s; \bar{x}, \mu)] \equiv \underbrace{F_Y(\bar{x}; s, \mu) \cdot V(0)}_{\text{Firm does not hire}} + \underbrace{\int_{\bar{x}}^{\infty} \frac{y}{1 - \beta} dF_Y(y; s, \mu)}_{\text{Firm hires}}, \quad (3)$$

⁴¹ This best match has CDF $F_Y(y; s, \mu) = \exp\{[F_X(y; \mu) - 1] \cdot s\}$: see [Bobotas and Koutras \(2019\)](#) and [Wilken \(2021\)](#).

⁴² For simplicity (and following [McCall, 1970](#)), we assume that, if the firm hires, the contract is permanent.

and, by the definition of the bounded reservation quality,⁴³

$$\bar{x} = \max [(1 - \beta) \cdot V(0), z]. \quad (4)$$

Together, equations 2, 3 and 4 describe the model, and capture its key trade-offs. The firm has two distinct reasons to hire: (i) an extensive margin impact (by hiring, the firm avoids the loss of κ), and (ii) an intensive margin impact (by hiring, the firm also gains y in every subsequent period). The firm invests in costly search activities ($s > 0$) in order to increase the number of matches – and, therefore, to improve the expected quality of the top candidate.

Depending on the values of the key parameters, this model is capable of generating several different types of behaviour – and, in particular, different comparative statics with respect to firm beliefs about worker quality. Specifically, we describe four distinct belief intervals. First, the model generates a ‘secure’ regime – in which, for sufficiently large μ , the firm optimally sets its reservation quality above the minimum (that is, $(1 - \beta) \cdot V(0) > z$), because it is confident that it can find a suitable employee. Here, a pessimism shock (decrease in μ) causes adjustment on two margins: the firm optimally lowers the reservation quality, and reduces search effort. Once the constraint binds – so that $(1 - \beta) \cdot V(0) < z$ and thus $\bar{x} = z$ – the firm’s only plausible response to a decrease in μ is to adjust search intensity. Adjustments in search intensity characterise the remaining three regimes. In the second regime, the firm sets its reservation quality at the cutoff ($\bar{x} = z$), but nonetheless anticipates a very high probability of filling the position; therefore a pessimism shock reduces the expected value of a hire, but does not appreciably affect the expected probability of hiring. In this regime, the firm optimally responds by reducing search; we term this the ‘confident’ regime. We term the third regime the ‘desperate’ regime. Here, the firm anticipates a meaningful probability that it will not hire. In this regime, the decrease in μ causes an *increase* in search expenditure. Given the relatively high cost of not filling the position ($\kappa \gg 0$) – and driven by the firm’s concern that it will not find a suitable candidate – a pessimism shock causes this to fall further, and the firm responds by increasing search in order partially to offset this. In the fourth regime, the firm is so pessimistic that it abandons search entirely ($s^* = 0$); we refer to this as the ‘no-search’ regime.

The predictions of the model therefore depend critically upon the regime in which a firm starts – and upon the magnitude of the pessimism shock. For example, if a firm

⁴³ That is, if the firm were unconstrained, it would set \bar{x} such that $V(\bar{x}) \equiv V(0)$. The firm chooses the greater of this value and the minimum reservation quality, z .

starts in the ‘secure regime’ (that is, the firm perceives a very high probability of finding a suitable candidate), a pessimism shock reduces the reservation quality. Depending on the magnitude of the shock, the impact on search may be negative (if the shock leaves the firm either in the ‘secure regime’ or the ‘confident’ regime), or can be positive (if the shock moves the firm sufficiently far into the ‘desperate regime’).⁴⁴

What about jobseekers? The model discussed above describes a firm searching for a prospective employee. The same stylised setup can readily be understood, *mutatis mutandis*, as describing search behaviour of our jobseekers. In the case of a jobseeker, x and y can be understood as referring to posted wages, \bar{x} as referring to the reservation wage, and $\kappa \gg 0$ can be understood as capturing the disutility from being unemployed. In the jobseeker context, we can think of $z \gg 0$ as a reference point below which the jobseeker is not willing to shift – driven, perhaps, by the leisure value of remaining unemployed, or by a distaste for low-status work (as documented, for example, by Groh et al. (2015) in Jordan).⁴⁵ Consider a jobseeker starting in the ‘desperate regime’. A pessimism shock increases job search but causes no change in the reservation wage ($\bar{x} = z$). The same result obtains for a jobseeker starting in the ‘confident regime’, who suffers a sufficiently large pessimism shock. However, for a jobseeker initially feeling quite comfortable about their search prospects (that is, starting in the ‘secure regime’), a sufficiently large pessimism shock causes a reduction in the reservation wage (from $\bar{x} < z$ to $\bar{x} = z$) while increasing search effort. This demonstrates that the model is able to account for the behaviour observed in our study: on both sides of the market – the firm side and the job-seeker side – a pessimism shock can lead to an increase in search effort and a decrease in the reservation quality.

5.2 Empirical evidence on the mediating role of beliefs

We now examine the evidence on the mechanisms that link our core results, namely, the treatment effects on beliefs and search effort and the labor market and recruitment outcomes. Our preferred explanation for these findings, formalized in the model above, can be summarized as follows: the firms moderate overoptimistic beliefs and reduce reservation

⁴⁴ As the model illustrates, the impact on search will – trivially – also be negative if the shock is so large as to move the firm into the ‘no-search’ regime.

⁴⁵ Indeed, on the jobseeker side, the model resonates with the recent non-stationary models of DellaVigna et al. (2017) and Marinescu and Skandalis (2020). Both of these models illustrate that search effort can increase as a jobseeker approaches the end of unemployment insurance. In some respects, the impending termination of unemployment insurance is analogous to a growing pessimism in our ‘unsafe regime’. For contrast, see Zuchuat et al. (2023), who provide a dynamic model in which jobseekers become more pessimistic when not finding a job, and reduce their search effort as a result.

quality; subjects search harder in response to these revised beliefs; and higher search effort and lower reservation quality cause an improvement in labor market and recruitment outcomes. We represent this causal chain in Figure 3.

Our reduced form results are also potentially consistent with two alternative models in which beliefs do not play a key mediating role. In both of these models — which we sketch in Figure B.6 and Figure B.7 — the job fairs activate a different mediator: they boost search effectiveness by the exchange of information among peers at the job fairs. For instance, jobseekers may learn about effective job-search strategies from talking to other jobseekers; and firms may learn about effective recruitment strategies from talking to other firms.⁴⁶ Higher search effectiveness in turn can cause an increase in search effort, and these two effects together can drive the impacts on downstream outcomes. In these alternative accounts, the revision in beliefs is either a side-effect of the impacts on search effort (Figure B.6), or it is an orthogonal margin of impact of the job fairs, unrelated to the causal chain that leads to improved outcomes (Figure B.7).

Our model differs from these two alternatives by positing that: (i) the job fairs directly impact beliefs; and (ii) beliefs directly impact search effort. Neither model B.6 nor model B.7 can account for both. Indeed, the model in Figure B.7 allows for (i) but not (ii), while model B.6 does not feature either of these casual effects.⁴⁷ Hence, to distinguish our preferred interpretation from these two alternatives, we need to show empirical support for both effects (i) and (ii).⁴⁸ We focus this analysis on jobseekers, for whom we have enough detailed data to study these causal mechanisms.

We start by providing evidence of causal channel (i) – i.e., that the impact on beliefs occurred as a direct result of the job fairs, not as an indirect consequence of changes in search effectiveness. We first note that there is no evidence of an impact on search effectiveness among the low-educated sample – i.e., those who increase their search effort: treated jobseekers and control jobseekers have similar conversion rates from applications to job interviews, and from applications to job offers (Table B.28). Second, we do not observe any evidence that jobseekers take concrete actions that would boost their search effectiveness. For example, they are no more likely to use a CV or to improve their CV. Third, we find no evidence that jobseekers increased their use of local job search networks,

⁴⁶ We thank an anonymous referee for suggesting this alternative mechanism.

⁴⁷ Model B.6 could potentially be augmented by adding the causal effect (ii) as a feedback loop from beliefs to search, without changing its main premise. But it would still not include causal link (i).

⁴⁸ Our preferred model can be enriched in multiple ways without changing the analysis required to distinguish it from the other models. For instance, we can allow for a feedback effect of search effort on beliefs or for a direct impact of the fairs on search effectiveness. Neither of these additions would eliminate the fact that, to support our model, we need to provide evidence on effects (i) and (ii).

an action that could have been stimulated by attendance at the job fairs and could have led to better employment outcomes. To demonstrate this, we collected dyadic network information at endline and we investigated whether more information sharing occurred within clusters of jobseekers invited to the job fairs.⁴⁹ We find no empirical support for this (see Table B.29). Fourth, we find no evidence suggesting that treated jobseekers change the type of occupations that they target: they are no more or less likely to search for (professional) office jobs or for (non-professional) manual work. This means that, overall, we find no empirical support for the most likely alternative mediator – job search effectiveness – or for its most likely drivers – peer-learning and job targeting. In contrast, we do find evidence of a substantial mismatch between jobseekers’ wage expectations at baseline and the wages offered by firms at the fairs (see Table 2). It would therefore be surprising if treated jobseekers did not update their beliefs after the substantial amount of interaction they had with firms at the job fairs, as discussed in Section 4.1. Taken together, the evidence supports the hypothesis that the fairs impacted beliefs directly, not through an impact on search effectiveness.

Next we examine the evidence we have on causal channel (ii), namely, that a pessimistic shock to beliefs increases search effort, as predicted in the desperate regime of our model. We would like to test this causal channel outside the context of the job fairs since, according to models B.6 and B.7, the fairs may have induced higher effort through a channel other than beliefs. Hence, we need a shock to beliefs other than the fairs. Given the limitations of the data, we do not have at our disposal an alternative shocks to beliefs that is experimentally assigned. But it is reasonable to assume that a longer search spell leads jobseekers to moderate their optimistic beliefs. Indeed, if we hold job quality and search intensity fixed, the time it takes a jobseeker to find a job is akin to a Poisson process. It is therefore quasi-random and can credibly be used as an instrument for jobseekers’ beliefs – provided that we control job quality and search intensity. This motivates an IV estimation strategy in which beliefs are instrumented by the time it took respondents to find their first job after the baseline interview. If this pessimistic shock to beliefs increases search effort, we should observe more search effort at endline for those who waited longer to find their first job after baseline.⁵⁰ This is indeed what we find: as shown in Table B.27, the instrument affects beliefs at conventionally accepted levels

⁴⁹ Since treatment followed a cluster-randomised design, all jobseekers in a given cluster were either invited to the job fairs or not.

⁵⁰ A potential concern regarding the validity of the IV strategy is that a longer search spell could exhaust jobseekers’ resources, thereby lowering future search intensity. To minimize this concern, we restrict the sample to individuals who were employed at least once during the course of the experiment and thus had an opportunity to replenish their financial resources while employed.

in most specifications and, most importantly, a downward revision in beliefs results in higher search effort. This lends additional support to the idea that a downward revision of beliefs can cause an increase in search effort, outside the context of the job fairs.

As a final test, we conduct a mediation analysis to estimate the share of the treatment effect on labor market outcomes that is attributable to a revision of beliefs. To this effect, we use a technique from [Acharya et al. \(2016\)](#) to calculate the Average Controlled Direct Effect (ACDE) of the job fairs on the likelihood of having permanent employment at endline. This exercise estimates the impact of the intervention, had beliefs not been affected by the fairs.⁵¹ Results, presented in [Figure B.8](#), show that the ACDE is 57% smaller than the actual impact of the fairs. This confirms that the impact of treatment on beliefs rationalizes a large share of the estimated treatment effects on final outcomes.

Before we end this Section, we note that our preferred interpretation of the empirical results is consistent with recent findings from the literature on job search. The literature has indeed demonstrated, both theoretically and empirically, that beliefs are a key driver of search effort elsewhere ([Spinnewijn, 2015](#); [Mueller and Spinnewijn, 2023](#)), thereby eliminating the possibility that beliefs affect search effort only in our context. The literature has also found that active labor market policies do not boost information sharing, contrary to what is assumed in models [B.6](#) and [B.7](#). For instance, a recent study reports that information sharing deteriorates – instead of improving – as a result of a job search intervention in the same geographical context as ours ([Caria et al., 2023](#)). Additional evidence on limited sharing of information on rival opportunities can be found in [Chiplunkar et al. \(2023\)](#). These recent findings provided additional support for our conclusion that peer-learning at the job fairs must have been limited.

6 Evidence from belief elicitation surveys

To provide further corroboration for our interpretation of the findings, we returned to the field to collect new data on the beliefs of representative samples of firms and workers. Our objective is twofold. First, we want to provide independent evidence on the over-optimism of workers and firms in this setting. This will help dispel concerns that the experimental results are an artefact of either selection (the fairs may have exposed individuals to a negatively selected sample of the other side of the market) or misinterpretation (the in-

⁵¹ This interpretation requires a technical assumption known as *sequential unconfoundedness*, which rules out the presence of intermediate confounders of the relationship between beliefs and labor market outcomes.

visitation to the fair may have been misinterpreted as signal of ability/quality). We take stock of all the evidence presented in the paper and further explore this possibility in Appendix A.3. Second, we want to collect data on a wider set of beliefs, in particular beliefs about the structural features of the labor market (e.g. the distribution of ability or wages). These beliefs are central in the definition of an optimal search strategy, but they are rarely investigated in surveys. Overall, we find clear evidence that, without our intervention, beliefs are systematically overoptimistic on both sides of the market. This provides strong support for our interpretation of the channels by which the intervention impacts firms and workers. It also supports our hypotheses that unrealistic beliefs contribute to the low levels of hiring at the job fairs and that the downward revision of beliefs caused by the job fairs did bring expectations closer to reality.

6.1 The belief elicitation surveys

Following up on our initial experiment, in 2019 we conducted a new belief-elicitation exercise with firm managers and jobseekers. Since our objective was to understand whether potential misperceptions exist among market participants in the absence of our treatment, we did not go back to the original sample that took part in the experiment but rather surveyed a new representative sample of jobseekers and firms. Specifically, we contemporaneously sampled firms that were advertising vacancies on Addis Ababa's job boards and jobseekers that were looking for vacancies at those job boards.⁵² The surveys have three unique features. First, they focus on a real, well-defined labour market. Second, they elicit beliefs on both sides of the market. While a number of papers study jobseeker beliefs, systematic data on the beliefs of firm managers is rare, especially in developing countries. Third, the surveys enable us to measure the accuracy of beliefs. In particular, we can contrast firms' answers with the true empirical counterparts obtained from the jobseeker survey and vice versa; this improves over existing studies that elicit beliefs but cannot measure their accuracy.⁵³

⁵² We interviewed 395 firm managers and 779 jobseekers. We recruited jobseekers between the age of 18 and 29, who had at least a high school diploma. We contacted a random sample of firms that were advertising a position on the job boards or in the newspaper between the end of November and the end of December 2019. We also contacted some of the firms that jobseekers were applying to. In this way, we selected samples of firms and jobseekers that resemble on key dimensions our original experimental participants.

⁵³ In addition, our surveys focus on new samples of market participants as opposed to the original experimental subjects. This has two distinct advantages over working with our original samples. First, attrition after several years may have biased our samples. Second, the subjects that took part in the intervention were exposed to the information they gained at the fairs. Our interest here is in uncovering perceptions biases that exist in the absence of the fair intervention.

The questionnaire for firms carefully elicits firm managers' beliefs about the ability of jobseekers – a key element of our model. Since our intervention produced heterogeneous effects by jobseeker level of education, we document expectations with respect to tertiary-educated applicants and high-school graduates separately. Ability is measured as a jobseeker performance on a Raven's test. We took a number of steps to make sure that lack of familiarity with such a test among firm managers does not distort our results. First, we provided the instructions for the test to the firm managers, so that they could familiarise themselves with it. Second, before managers answered the ability questions, we provided them with real statistics on the difference in test score between workers with a high (75th percentile) and an average GPA in our sample. This served the purpose of giving employers a sense of how test results correlate with an observable characteristic (GPA) commonly used in hiring, thereby providing an anchoring reference point. In addition to measuring expectations about jobseekers' ability, we also elicited managers' beliefs about the jobseekers' reservation wages and their work experience. This elicitation exercise was incentivised.⁵⁴

The questionnaire for jobseekers focuses on their reservation wage, their belief about the distribution of wages across sectors, and their belief about job-finding probabilities. We elicited beliefs about the distribution of wages by asking the jobseeker what proportion of jobs currently advertised pay a wage lower than a set of thresholds (from 10,000 ETB to 1,000 ETB per month). Similarly, we elicited reservation wages by asking the jobseeker whether they would accept a job that pays at least a certain amount. This amount was decreased until we found the wage bracket corresponding to the jobseeker's reservation wage. To minimise complexity, we did not incentivise the elicitation of beliefs among jobseekers. Finally, after the belief-elicitation was completed, jobseekers took a 12-item Raven test.

In light of our theoretical model, we use the data from the survey to investigate the hypothesis that firm managers and jobseekers may have distorted perceptions about the quality of available matches. For firm managers, we test this by comparing their perceptions about the quality of jobseekers (i.e., their ability) with the actual distribution of ability in our sample. For jobseekers, we test whether their beliefs about the expected duration of unemployment and the quality of available jobs (proxied by wages) align with reality. We also test how their reservation wages compare with prevailing wages.

⁵⁴ Participants were told that one of the questions they were asked would be randomly drawn at the end of the survey and they would receive a prize based on the accuracy of their answer.

6.2 Distorted beliefs among firm managers

From the belief elicitation survey of firms, we find clear evidence of distorted beliefs among managers. Our first result is that firm managers overestimate the ability of jobseekers. We asked firms to predict how many questions on a Raven’s test can be answered correctly by a representative individual with high school or tertiary education, respectively. These questions were asked after first familiarizing firm respondents with the test itself. Figure A.2 shows that 65% of firms overestimate the average Raven’s test scores for workers in the educational category for which they are currently hiring. Firms’ average forecast of tests scores is higher than the true average — a result entirely driven by managers overestimating the ability of workers with tertiary education. This is illustrated in Figure B.2 through a series of ‘raincloud plots’ of managers’ beliefs, with superimposed vertical lines showing the average jobseeker characteristic. Firm respondents also overestimate the ability gap between tertiary and secondary-educated jobseekers. The average secondary-educated and tertiary-educated jobseekers correctly answer 5 and 5.3 questions on the Raven test, respectively. By contrast, the median firm forecasts that secondary-educated jobseekers correctly answer 4 questions vs. 6 questions for tertiary-educated jobseekers. In other words, the true ability premium associated with tertiary education is less than one fourth of what firms expect. Furthermore, the perceived difference between the two groups is twice as large as the difference in Raven performance between individuals at the 75th percentile and at the mean of the GPA distribution – the anchoring information we gave to firms before these forecasts. Overall, almost 75% of firms overestimate the ability of tertiary-educated jobseekers and about 90% of them overestimate the ability premium associated with tertiary education. Because most firms in our sample are trying to hire workers with tertiary education, the average firm in the sample overestimates the ability of the types of worker they are trying to hire – a finding that is summarised in Figure A.2.

Additionally, we find that firms overestimate work experience and reservation wages among tertiary educated jobseekers. More than 75% of managers overestimate the share of tertiary-educated jobseekers who have at least two years of work experience (Figure B.2). The median manager expects about 20 percent of tertiary-educated workers to have two years of work experience, a figure that is almost twice the actual proportion. Furthermore, in the survey, we ask firm respondents to indicate the proportion of jobseekers who would accept different wage levels for the most common job available at the firm. Figure A.3 shows that firms overestimate the reservation wages of tertiary-educated jobseekers across occupations – but most starkly with respect to professional roles. Finally, as was the case

for ability, the patterns for secondary-educated workers are reversed: firms underestimate both their work experience (e.g. Panel B of Figure B.2) and their reservation wages (Figure B.3).

In sum, firms on average overestimate the ability and work experience of the jobseekers they are trying to hire. This shows unequivocally that beliefs are inaccurate in a representative sample of recruiters. These findings thus help explain why hiring at the job fairs was modest: firms were disappointed by the quality (both in terms of raw ability and work experience) of the tertiary-educated jobseekers they met and hence made few if any offers; at the same time, they underestimated the ability and reservation wages of the secondary-jobseekers they met and, consequently, made offers to this group that were rejected. This interpretation is further supported by clear evidence that past experience is highly sought after by firms. The most common reason firms report for not hiring more at the fair is ‘insufficient work experience’ (34% of firms). Other common reasons relate to the perceived expertise of workers or poor interview performance (see Table B.20). Educational mismatch plays a role, but is certainly not the most important factor. Furthermore, dyadic analysis of firm-requested meetings shows that past experience is the strongest predictor of firms’ meeting requests – and the effect is strongest among workers with tertiary education, in line with the rest of the evidence.⁵⁵

Overall, the evidence from the belief-elicitation firm survey is thus consistent with the hypothesis that the firms that came to the job fairs had incorrect beliefs about the experience levels of tertiary-education candidates and about the quality and reservation wages of secondary-educated candidates. It is therefore reasonable to assume that, by allowing firms to interact with a large number of such candidates at once, the fairs gave them an opportunity to update their beliefs. This is indeed what we showed earlier in this paper: Section 4.2.3 documented that treated firms became more pessimistic about the number of workers they would hire in the next 12 months; and Table 6 showed that treated firms became more pessimistic about hiring both types of workers, but especially those in occupations that typically require tertiary education. This, in turn, led firms to revise their search strategy in the direction predicted by our model, that is, by increasing their search effort.

⁵⁵ We apply the same dyadic regression approach as in equations (5) and (6) and report the results in Table B.21. The dependent variable is $request_{fj}$, a dummy equal to one if firm f requested a meeting with jobseeker j , using a centralized meeting-request algorithm that we offered to firms at the fair. Regressors include jobseeker and firm characteristics. The results are not driven by firms who sought experienced jobseekers outside the fair: even firms willing to hire graduates without work experience at baseline are more likely to request experienced jobseekers at the fair.

6.3 Distorted beliefs among jobseekers

Turning to jobseekers, the belief elicitation survey provides clear evidence of over-optimism on the probability of finding a good job. The evidence is particularly strong for secondary-educated jobseekers. These jobseekers overestimate both the probability of obtaining a permanent job with an open-ended contract, as well as the probability of obtaining a professional job. We discuss each of these findings in turn.

First, we present evidence on the probability of securing a permanent job. Figure 5 compares jobseekers' perceived likelihood of finding a permanent position with data on the actual likelihood of getting a permanent position in the control group of our experimental sample.⁵⁶ We see that 55% of jobseekers with a high-school diploma expect to find a job with a permanent contract in less than 1 year. In reality, only 5.8% of such candidates on our experimental sample found a permanent job within 1 year. Furthermore, when asked about jobseekers in the same age cohort with the same education and work experience, respondents expect 30% of them to find a permanent job within one year. This suggests that jobseekers with a high-school diploma are not only over-confident about their own ability relative to the rest of their cohort, they are also over-optimistic about the average prospects of individuals *like themselves*.

Second, we present evidence on the probability of securing a professional job. In the survey, we asked jobseekers who were targeting high-skilled jobs in managerial, technical or professional positions, who they thought would eventually get that job. Among jobseekers who did not complete a tertiary degree, less than 20% believe that the vacancy would eventually be filled by someone with a tertiary degree. Furthermore, only a fifth of them think that a tertiary degree is a requirement for the job. This differs markedly from what is reported by the firms participating in the belief elicitation survey: 71% of high-skilled vacancies have degrees as a minimum requirement, and 74% eventually go to someone with a tertiary degree. Similarly, half of the jobseekers think that no previous work experience is required for securing a high-skilled job and 36% think that the job will go to someone without any formal work experience. In reality, surveyed firms report that only 16% of

⁵⁶ Since we only interview jobseekers once, we do not have data on the length of their unemployment spell in the most recent survey and we have to resort to the experimental sample. We believe this provides a valid benchmark. First, the two populations were selected using similar screening criteria based on age and education. Thus, when we re-weight by observables to ensure comparability between the two samples, there are no qualitative changes in our findings. Second, although the two samples were interviewed a few years apart, aggregate labour market conditions are not significantly different between the two periods. Third, to drive the observed divide between more educated jobseekers and less educated ones, labour market conditions should have varied differentially for different groups of workers. We have no evidence of that occurring.

high-skilled jobs require no formal experience while 59% of these jobs require two or more years of experience.

On the other hand, jobseekers' beliefs about the distribution of wages paid for available jobs are well-aligned with reality. When asked about average wages in different occupations, the answers respondents provide closely track prevailing wages in different sectors (Figures B.4 and B.5). Jobseekers with secondary education also have fairly accurate beliefs about the distribution of wages in specific occupations (Figure B.4). The same is true for jobseekers with tertiary education who, if anything, overestimate the proportion of jobs at the bottom of the wage distribution (Figure B.5).

What are the implications of these beliefs for the search strategies chosen by jobseekers? We find that jobseekers, in particular those with secondary education only, set unrealistic reservation wages and target jobs that they are unlikely to get. In terms of reservation wages, we find that 70% percent of jobseekers with only a high-school diploma and no permanent work experience state they would reject a job paying 2000 ETB per month, even though 44% of jobs for that occupation and level of experience pay less than 2000 ETB per month. Jobseekers with secondary education also often seek positions for which firms largely hire tertiary educated jobseekers and which, therefore, they are unlikely to get. Figure 4 shows this clearly. A large proportion of jobseekers with secondary education (Panel A) seek employment in professional categories such as 'Technicians and professionals' and 'Services and sales workers', even though firms offer few opportunities in those roles to jobseekers with only secondary education. Overall, these findings are consistent with the behavior of secondary-educated jobseekers at the job fairs: these jobseekers rejected job offers that were largely for non-professional jobs and paid less than their high reservation wages. Recall that in our experiment it is the sample of less-educated jobseekers who updated their beliefs and changed their search strategies in response to attendance at the job fairs.

Why young jobseekers hold incorrect beliefs is unclear, but one possible explanation is that their expectations partly reflect the experiences of older relatives who entered the labor market at a time when tertiary education was more scarce and hence a larger share of positions was open to those with secondary education. This misperception may in turn be concentrated in the secondary-educated sample as students attending tertiary education are likely to have access to better labor-market information from lecturers, career support, or employed peers.

7 Conclusion

We run a novel experimental job fair, with a unique dual randomization – both on the side of jobseekers and of participating firms. The invited jobseekers are representative of the young jobseekers whom firms usually hire, and participating firms are a representative sample of large employers. We facilitate interactions between jobseekers and firms by providing information about jobseekers’ education and firms’ vacancies, and by suggesting matches based on a Gale-Shapley algorithm. We study both the immediate effects of the treatment on jobseekers’ and firms’ outcomes, and subsequent effects – on both search strategies and expectations.

We find that the fairs generate a rich set of interactions between jobseekers and firms, and that the matching algorithm is successful in increasing the efficiency of the matching process. The immediate impact of the treatment on employment outcomes is limited with few hires made at the fair, but we find clear evidence of delayed effects of treatment, as both firms and jobseekers learn from the information they acquire at the fairs: they change their expectations accordingly and adjust their search strategies. Treated jobseekers with at most a high-school diploma had misaligned reservation wages prior to treatment; after the fairs, they search harder, lower their reservation wages, and experience a significant increase in their probability of obtaining a formal job at endline (6 months after the second fair). Treated firms increase their search efforts and substitute away from tertiary educated workers on whom they had overly optimistic expectations at baseline. A follow-up belief-elicitation exercise with similar jobseekers and firms confirms both that firms have overly optimistic perceptions of the skills of jobseekers with tertiary education, and that jobseekers have overly optimistic beliefs about the probability of obtaining professional jobs given their qualifications.

The main contribution of our paper is to show that both firms and jobseekers hold inaccurate beliefs about market fundamentals – that is, labour market participants suffer not merely from a problem of information asymmetries, but from deeper misperceptions of the distribution of important traits among other market participants. These misperceptions appear to be distorting job search decisions in a way that could have important implications for the workings of labor markets. We find that, by facilitating rich interactions between the two sides of the market, the fairs serve to reduce these deep misperceptions: when attending the fairs partially corrects these misperceptions, both sides of the market reoptimise their search strategies. Our results show that active labour market policies that increase contact between jobseekers and firms – such as job fairs, and including many other classes of policy interventions – are able to generate important learning effects on

both sides of the market, an effect that is particularly relevant in the rapidly expanding urban labor markets of growing cities in the Global South.

Manufacturing	24.4	149.0	37.4	33.7	250.2	69
All Industries	26.9	52.4	33.1	52.8	171.5	493

Notes: This table describes the firms in our sample, disaggregating by primary sector and by type of occupations.

Table 2: **Mismatched expectations: Reservation wages of workers before the fairs, wages offered at the fairs, and endline employment outcomes (Medians)**

	Education of worker			
	High-school	Vocational	Diploma	Degree
<i>Panel A: Workers' reservation wages, and firms' wages for jobs offered at the job fairs</i>				
Worker reservation wages before fairs (birr)				
With experience (13%)	1500	2000	2000	3000
Without experience (87%)	1300	1500	1600	2500
Firm wages for positions at fairs (birr)				
Require experience	1588	1900	3250	5685
Don't require experience	855	1018	1168	3500
All jobs	973	1500	2900	4500
<i>Panel B: Workers' expectations at baseline</i>				
Expects at least one job offer in next four months				
All experience levels	73%	72%	74%	72%
With experience	81%	72%	82%	72%
Without experience	73%	72%	72%	73%
Expected wage "for someone like me one" year from now (birr)				
All experience levels	1400	1600	1800	2500
With experience	1500	1900	1900	3400
Without experience	1400	1500	1800	2500
<i>Panel C: Workers' employment outcomes at endline (control group)</i>				
Worker employment rates at endline				
All jobs	50%	56%	43%	69%
Permanent jobs	6%	17%	19%	35%
Worker wages at endline by experience (birr)				
All experience levels	1000	1400	1500	2300
With experience	1450	1450	1743	3000
Without experience	975	1400	1350	2100

Notes: This table describes self-reported reservation wages (for jobseekers) using phone survey data in the weeks just prior to the first job fair, offered wages at the job fair (for firms), and endline wages (for jobseekers in the control group), disaggregated by types of worker and type of job.

Table 3: **Firm recruitment methods**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firm performed formal interviews (professionals)	0.0440 (.038) [.115]	0.682	473
Firm performed formal interviews (non-professionals)	-0.0140 (.039) [.313]	0.607	473
Did any advertising for new hires	0.0580 (.032)* [.074]*	0.789	473
Did advertising for professional positions	0.120 (.038)*** [.011]**	0.595	473
Did advertising for non-professional positions	-0.0620 (.033)* [.074]*	0.194	473
Did advertising on the job boards	0.0960 (.042)** [.055]*	0.331	473

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. The variable "Did any advertising for new hires" encompasses advertising for both professional and non-professional positions. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Table 4: Workers' job search and employment outcomes after the fairs

	(1)	(2)	(3)	(4)	(5)

Test High=Post (p)	0.118	0.718	0.018	0.116	0.577

Notes: Each row reports a separate regression. The outcomes are measured 6 months after the fairs. 'Wage mismatch' refers to the absolute difference between the worker's reservation wage (in logs) and the expected wage for a worker of that skill/education level (in logs). For each regression, we report the estimated ITT from participating in the job fair (disaggregated, in Panel B, by whether the worker has post-secondary education or merely high school). Standard errors are reported in parentheses. In the bottom row, we report p-values for a test of the null hypothesis that the effect of treatment is equal between high-school and post-secondary sub-samples.

Table 5: Workers' expectations after the fairs

ControlSD PostSecond	0.600	1.005	0.587	1.613	0.193	0.962
Test High=Post (p)	0.278	0.326	0.283	0.240	0.010	0.506

Notes: Each row reports a separate regression. The outcomes are measured 6 months after the fairs. Res Wage is the reservation wage in logs. 'Wage mismatch' refers to the difference between the worker's reservation wage and the expected wage for a worker of that skill/education level, expressed as percentage of expected wages, and normalised to have mean zero and standard deviation of one. 'Highest wage' is workers' report of the highest wage they could expect to receive if they got a job in the next 12 months, in logs. 'Offers expected' is the number of job offers expected in the next 4 months. 'Searching for permanent job' is a dummy equal to 1 if the main job the worker is looking for is permanent. "Likelihood job" is a likert-scale response to the question: "What do you think the chances are that you will have found a job in the 12 months?". For each regression, we report the estimated ITT from participating in the job fair (disaggregated, in Panel B, by whether the worker has post-secondary education or merely high school). Standard errors are reported in parentheses. In the bottom row, we report p-values for a test of the null hypothesis that the effect of treatment is equal between high-school and post-secondary sub-samples.

Table 6: **Firms’ expected number of future hires after the fairs**

<i>Outcome</i>	Job Fair	Control Mean	N
<i>Panel A: Aggregate hiring expectations</i>			
All	-13.33* (7.049)	45.63	472
<i>Panel B: Hiring expectations by occupational type</i>			
Higher-education positions	-9.691* (5.337)	33.87	419
Lower-education positions	-5.051 (3.55)	14.66	415

Notes: The outcome variable is the number of workers the firm expects to hire in the following 12 months in different occupations, measured 6 months after the fairs. Higher Educ. includes "Professional/Managerial" and "Client Service" occupations, which typically require higher levels of education. Lower Educ. includes "Production Workers" and "Support Service" occupations. All includes workers in all occupational categories. Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses.

Figures

Figure 1: Output of the matching algorithm

Notes: This figure illustrates the outcome of the matching algorithm. Each point represents a stable match recommended by the algorithm. The figure shows which combinations of firm rankings and job-seeker rankings generated these recommended matches. The graph provides a visual illustration that the algorithm worked well in the sense of generating matches between firms and job-seekers who are, on the basis of job-seeker skills and experience, reasonably well-suited to each other.

Figure 2: Impacts on Job Search by Fortnight

Notes: This figure shows the probability, for each fortnight, that treated job-seekers visit the job board, relative to job-seekers in the control group. Fortnight 0 is when the first job fair was held; the second fair was held in fortnight 8. We estimate the difference in probabilities using a Linear Probability Model in an ANCOVA specification, in which we regress job search on treatment, baseline search status and a vector of baseline balancing variables. We cluster at the level of individual job-seekers, and show both point estimates and 90% confidence intervals; we do this both by regressing on fortnight dummies, and by imposing a quadratic shape.

Figure 3: Stylized causal chain

Figure 4: Distribution of occupation sectors

Note: Data from our follow-up survey on beliefs. This figure shows the distribution of (i) the proportion of total jobs in the most common occupations in each firm, and (ii) the sector of the job most commonly looked at by job-seekers in the last week. We show both bars for the five most common sectors for the firm side. We report D_{KL} , the Kullback-Leibler distance from the distribution of jobseeker sectors to the distribution of firm occupation sectors.

Figure 5: Jobseekers' expectations of finding a job with a permanent contract in the next 12 months

Note: 'Expectation: Self' refers to jobseekers' stated probabilities that they will be employed with a permanent contract in the next 12 months, as measured in our follow-up survey on beliefs. 'Expectation: Other' refers to jobseekers' stated probabilities that others like them will be employed with a permanent contract in the next 12 months, as measured in our 2019 follow-up survey. 'Actual' refers to the actual proportion of jobseekers who found a job with a permanent contract, using our original survey data.

Online Appendix

A Theoretical model: Further details

As the main text explains, the model is described by equations 2, 3 and 4:

$$V(0) = \max_{s \geq 0; \bar{x} \geq z} -\kappa - \alpha s + \beta \cdot \mathbb{E}[V(y | s; \bar{x}, \mu)], \quad (2)$$

where

$$\mathbb{E}[V(y | s; \bar{x}, \mu)] \equiv \underbrace{F_Y(\bar{x}; s, \mu) \cdot V(0)}_{\text{Firm does not hire}} + \underbrace{\int_{\bar{x}}^{\infty} \frac{y}{1 - \beta} dF_Y(y; s, \mu)}_{\text{Firm hires}}, \quad (3)$$

and, by the definition of the bounded reservation quality,⁵⁷

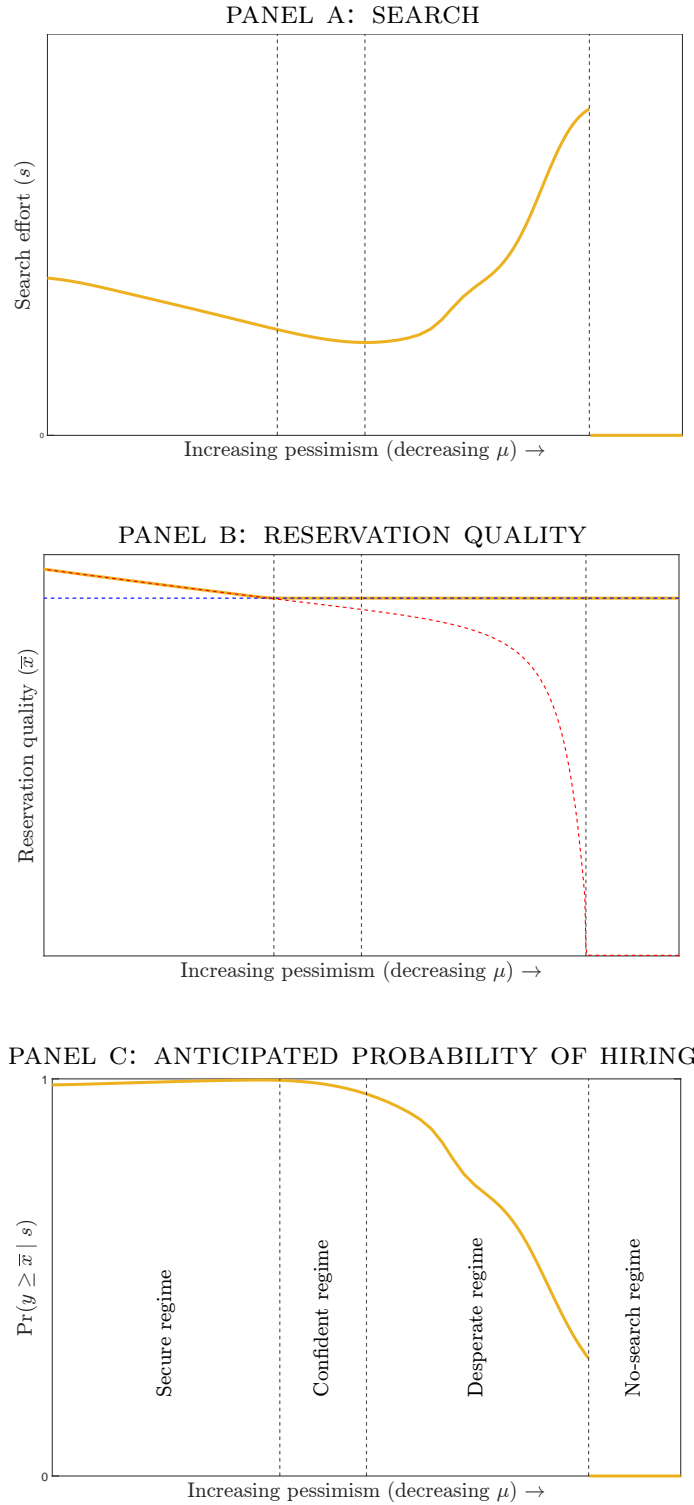

$$\bar{x} = \max[(1 - \beta) \cdot V(0), z]. \quad (4)$$

We solve this model using a standard value function iteration (where we evaluate $\mathbb{E}[V(y | s; \bar{x})]$ using a Monte Carlo integration). For our numerical implementation, we use the Exponential distribution for x ; that is, we use $F_x(x; \mu) \equiv 1 - \exp(-x/\mu)$. In Figure A.1, we consider a regime with particular relevance to our experimental results, using relatively large values for both κ and z . For this illustration, we use $\alpha = 1$, $\beta = 0.95$, $\kappa = 50$ and $z = 3.5$.

On the horizontal axis of each panel, we show μ – with higher values of μ to the left, so that a move to the right indicates a more pessimistic firm belief. (Specifically, we graph values for μ from $\mu = 3$ down to $\mu = 0.1$.) Panel A shows the firm’s optimal choice of search effort, s . Panel B shows the firm’s reservation quality, \bar{x} ; specifically, it shows both z , as a dotted blue line, and $(1 - \beta) \cdot V(0)$, as a dotted red line; the solid orange line is therefore the upper envelope, \bar{x} . Panel C shows the firm’s anticipated probability of hiring, given its beliefs: $\Pr(y \geq \bar{x} | s)$.

⁵⁷ That is, if the firm were unconstrained, it would set \bar{x} such that $V(\bar{x}) \equiv V(0)$. The firm chooses the greater of this value and the minimum reservation quality, z .

Appendix Figure A.1: Model predictions

This figure shows the key predictions of our dynamic search model. Specifically, it shows numerical results obtained by a value function iteration (and using a standard Monte Carlo integration). We use the Exponential distribution: $F_x(x; \mu) \equiv 1 - \exp(-x/\mu)$, and set $\alpha = 1$, $\beta = 0.95$, $\kappa = 50$ and $z = 5$. The horizontal axis shows values for μ from $\mu = 3$ down to $\mu = 0.5$. The panels respectively show (i) the firm's optimal search effort, s (Panel A), (ii) its reservation quality, \bar{x} (Panel B), and (iii) the resulting probability of hiring, $\Pr(y \geq \bar{x} | s)$ (Panel C). Panel B shows both z , as a dotted blue line, and $(1-\beta) \cdot V(0)$, as a dotted red line; the solid black line is therefore the upper envelope, \bar{x} .

Appendix Figure A.2: **Distribution of manager’s forecast error on jobseekers’ average Raven’s test score**

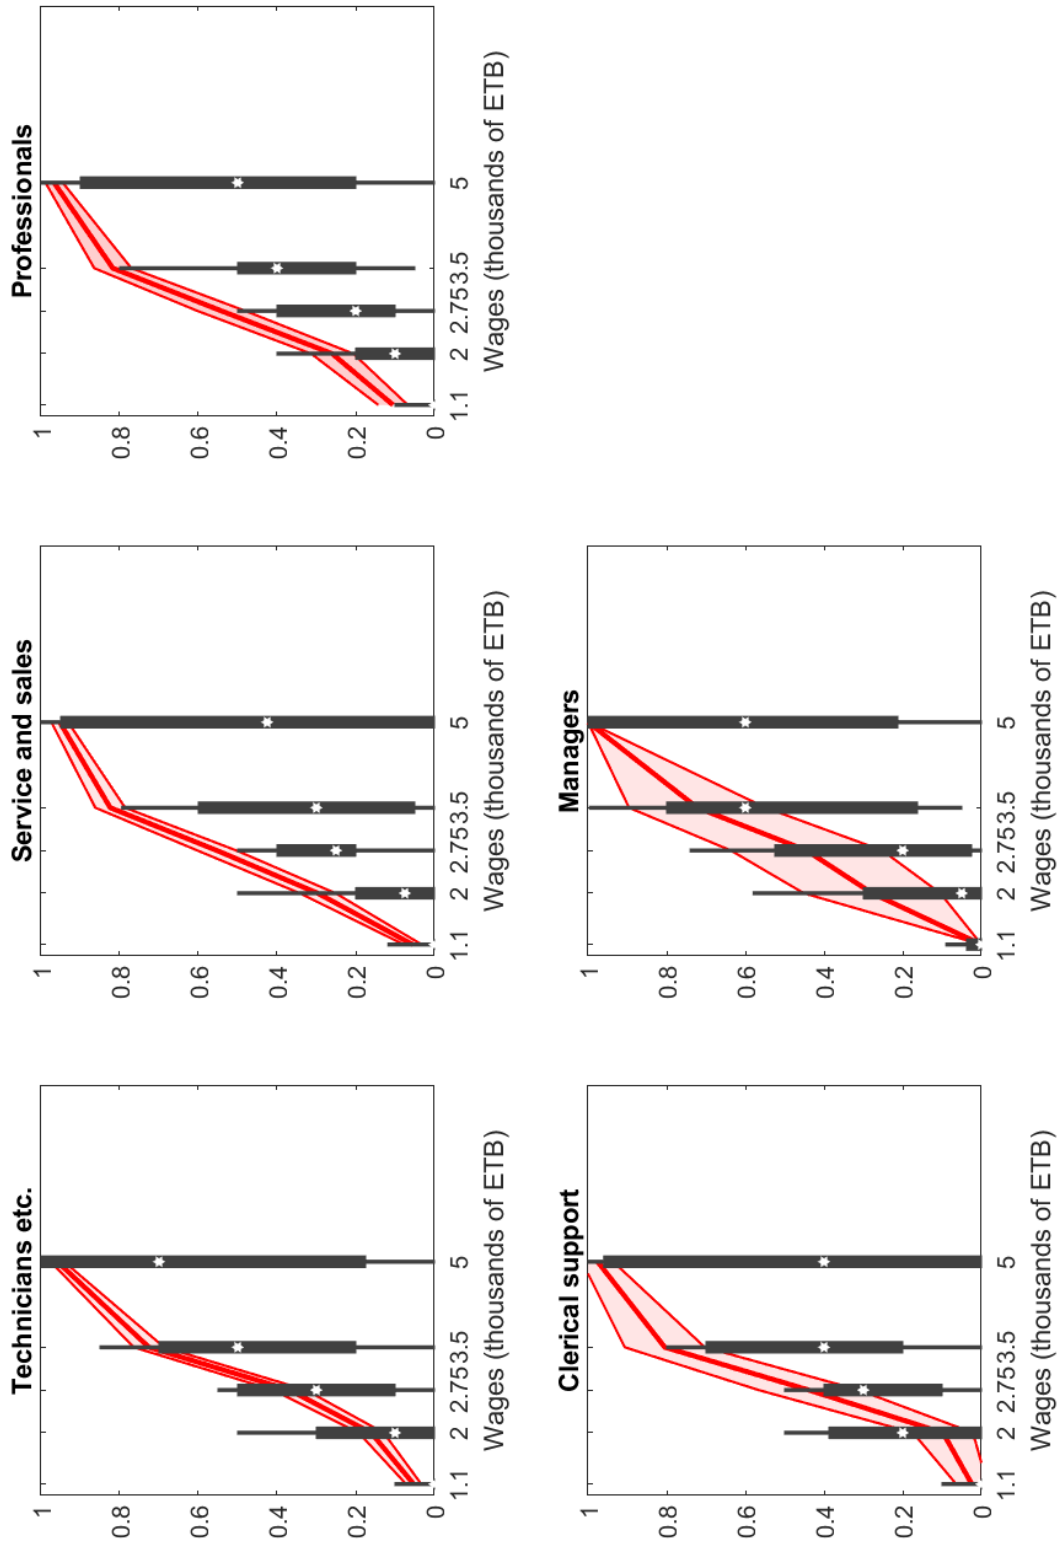

Notes: The forecast error is computed as the difference in percentage points between a manager’s belief about the average score of workers in the educational category (high school or tertiary education) most sought after among current vacancies open at the firm, and the actual average score of workers in that educational category.

A Robustness Checks

A.1 Was the market at the job fairs too thin?

One possible explanation for this small direct effect is the market at the job fairs was too thin: there were too few high-quality worker-firm matches available. We present evidence against this hypothesis both from the jobseeker and the firm side. First, we investigate whether the jobs on offer were too few or did not match jobseekers’ interests. To study this issue, we use data that was collected from participating firms prior to arriving at the

Appendix Figure A.3: Firms' beliefs about the distribution of job-seekers' reservation wages: Tertiary-educated job-seekers

Notes: These figures show the distribution of firm beliefs about job-seekers' reservation wages. In each graph, we show this at five wage points: in each case, we show the distribution of firm beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our job-seekers with a given reservation wage (where the shaded area represents the 90% confidence interval for the proportion).

fairs. Firms were to provide a roster of all their open vacancies at the time of the fairs.⁵⁸ The average firm at the fair had two vacancies open and was looking to hire seven workers. 70% of participating firms had at least one vacancy. In total, there were 711 vacancies and 1,751 jobs available at the fairs. The occupational composition of the vacancies exhibits considerable overlap with the distribution of occupations desired by jobseekers invited to the job fairs. It is therefore unlikely that firms did not have enough vacancies of the kind that jobseekers wanted.

Second, we investigate whether jobseekers were negatively selected and hence firms were reluctant to hire them. To explore this possibility, we compare the jobseekers who attended (about 60% of those invited) to those in the full sample, which is near-representative of educated young jobseekers in Addis Ababa at the time of the study. In Appendix Table B.8 we regress attendance at the fairs on a rich set of baseline characteristics. We find no evidence suggesting that observably weaker candidates are more likely to attend the fairs: education and current employment do not significantly predict attendance. The only two robust predictors of attendance are instead associated with a positive motivation to work: attendance is higher among those jobseekers who search the most at baseline and who produce a formal certificate to employers.⁵⁹ Further, in the second job fair, we showed firms the list of qualifications of jobseekers at the fair and asked them whether they were interested in interviewing some of them. Most responded positively and provided the names of several candidates of interest to them. Across both fairs, firms report meeting 20 jobseekers on average. We can therefore rule out that firms were in principle uninterested in the jobseekers that attended the fairs.

A.2 Did the fairs suffer from congestion and mis-coordination?

Since both employers and jobseekers were interested in each other and willing to interact, could the small direct effect of the fairs be due to congestion and miscoordination? That is, could the effect be explained by firms and jobseekers having wasted their time and effort talking to the wrong people? To investigate this possibility, we test whether the jobseeker-firm pairs that met are those that were most suitable for each other, given the mix of employers and jobseekers at the fairs. We use two types of variables to assess mutual suitability: the synthetic rankings, and the proposed matches that we suggested to participants. The two ranking variables are Rank_{fj} , which is firm f 's ranking of jobseeker j , and Rank_{jf} , which is jobseeker j 's ranking of firm f . The two proposed match variables are: Gale_Shapley_{jj} , which is equal to 1 if jobseeker j and firm f were recommended to each other by our Gale-Shapley algorithm, and Random_{jj} , which is 1 if jobseeker j

⁵⁸ We define a vacancy as an open position for a specific occupation. Firms first produced a list of vacancies (e.g. a firm could report that they were both looking for clerical workers and for drivers) and, then, for every vacancy, they reported the number of workers they were planning to hire in that position.

⁵⁹ Invitees already in permanent employment at the time of the fairs are slightly less likely to attend. But the effect is unlikely drive our results: 4% of those attending the fairs have a permanent job compared to only 5.6% of the total sample.

and firm f were randomly recommended to each other by us. If firms and jobseekers are able to engage in promising interactions, we expect participants’ rankings to predict who wishes to meet with whom and who actually meets whom. If our matching algorithm was capable of identifying promising matches instead of random matches, we expect meetings and willingness to meet to be predicted by `Gale_Shapleyfw` but not by `Randomfw`.

To test these hypotheses, we estimate two dyadic regression models:

$$y_{fj} = \beta_0 + \beta_1 \cdot \text{Rank}_{fj} + \beta_2 \cdot \text{Rank}_{jf} + \mu_{fj}; \quad (5)$$

$$y_{fj} = \beta_0 + \beta_1 \cdot \text{Gale_Shapley}_{fj} + \beta_2 \cdot \text{Random}_{fj} + \mu_{fj}, \quad (6)$$

where y_{fj} is either $request_{fj}$, a dummy equal to one if firm f requested a meeting with jobseeker j , or $meet_{fj}$, which equals one if firm f and jobseeker j actually met. Standard errors are clustered two-way at the level of the firm and jobseeker (Cameron et al., 2011).

We report estimates in Table A.1, using the jobseekers and firms who attended the fairs. We find that the synthetic rankings predict both requested meetings and actual meetings. The effects are large and significant. Moving from the highest to the lowest rank is associated with an almost 100 percent decrease in the probability of a requested meeting, and about a halving of the probability of an actual meeting. We interpret these results as showing that the fairs are effective in bringing together jobseeker-firm pairs who – at least on the basis of observable characteristics – value each other. Algorithmic recommendations are also shown to have a strong predictive power: matches suggested by our algorithm are about 200 percent more likely take place than non-suggested matches. In contrast, the coefficient on randomly suggested matches is small and never significant. This contrast suggests that our stylized matching algorithm was useful in identifying matches that were deemed worth pursuing by market participants. The fairs thus appear to have reached their objective of facilitating meetings between jobseekers and the firms that suited them best.

This interpretation is supported by comparing the application-to-interview and interview-to-offer rates at the fairs versus in the open market. First, in the open market, job-seekers secured an interview for every 3.5 job applications, an offer for every 1.9 interviews, and a job for every 3.3 interviews over the period between the baseline and endline surveys. This implies that contacts with employers at the fair (20 on average) were much less likely to result in an interview than a formal job application. The contrast is particularly striking for highly educated job-seekers, who tend to do better in the labour market but did particularly poorly at the fair. Second, the 1.4 conversion rate of interviews into offers compares favorably to the 1.9 conversion rate observed outside the fairs. Third, the conversion of interviews into jobs is much lower at the fair: one job for 7.5 interviews instead of 3.5 outside the fairs. A large majority (81%) of offers made in the aftermath of the fairs were rejected. To verify these findings, we conducted a phone survey of firms immediately after each job fair. Appendix Tables B.14 and B.15 show the immediate impact on overall hiring and the type of job candidate hired, respectively. These results confirm that the fairs had no significant impact on short-term hiring by treated firms.

A.3 Did the job fairs create artificially negative signals or did they correct miscalibrated beliefs?

Did the fairs help individuals generate more accurate beliefs about the labor markets, or did they send misleading signals? In this section, we consider two possible ways in which the fairs may have generated misleading signals. First, the fairs may have exposed firms and jobseekers to non-representative samples of market participants. For example, if the vacancies available at the fair were more competitive than the average vacancy on the market, workers may have incorrectly inferred a negative signal about the likelihood of being offered a job for the average vacancy. Second, matching at the fairs may have been of low quality, possibly due to poor logistics or to difficulties for workers to locate employers. If subjects were disproportionately exposed to mismatched counterparts, they may have wrongly perceived a negative signal about poor labour market fundamentals.

Overall, our evidence is not consistent with either of these stories. First, we note that both our baseline data and the belief elicitation surveys demonstrate that both firms and jobseekers do indeed hold overoptimistic beliefs about the other side of the market (Section 2.3 and Section 6). Additionally, our descriptive evidence does not lend support to either the selection or the mismatch story. First, to address the selection concerns, we show in Sections 2.1, 2.2, 3.2 and A.1 that (i) the samples invited to the fairs were fairly representative of the broader population of jobseekers and firms, and (ii) that selection on take-up was limited. Second, regarding matching, Section A.1 and Section A.2 show that the meetings that took place at the fairs were positively selected on expected match quality, which moderates concerns related to poor match quality. In sum, our analysis shows direct evidence of overoptimism from two different datasets, and does not lend support to the hypothesis that signals were distorted by either selection or mis-match. Based on this evidence, we conclude that it is unlikely that the job fairs generated misleading signals on market fundamentals.

Appendix Table A.1: Dyadic regressions: Rankings, matches and meetings

	Requested (1)	Actual (2)	Requested (3)	Actual (4)	Requested (5)	Actual (6)

Notes: This table provides basic descriptive statistics on sample firms; in doing so, it also shows the variables used for blocking and re-randomisation. The 'p-value' column shows individual p-values for tests of covariate balance.

Appendix Table B.5: **Worker employment amenities**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Received job by interview	0.0270 (.141) [1]	0.167	1702
Office work (7d)	0.00700 (.803) [1]	0.201	1702
Skills match with tasks	-0.0380 (.219) [1]	0.130	1702
Overqualified	0.0290 (.395) [1]	0.291	1702
Underqualified	-0.0130 (.468) [1]	0.0820	1702

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.6: **Worker job search outcomes**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Applied to temporary jobs	0.242 (.347) [.533]	1.311	1693
Applied to permanent jobs	-0.0670 (.749) [.713]	2.279	1692

Any Job			-0.00143 (0.0338)	-0.00576 (0.0335)
Constant	0.748*** (0.253)	0.398*** (0.0376)	0.631*** (0.0270)	0.664** (0.263)
Observations	1,006	1,006	1,006	1,006
R-squared	0.018	0.045	0.007	0.063

Note: This table reports regression coefficients from a Linear Probability Model, in which we regress attendance at the fairs on a rich set of baseline characteristics; we provide robust standard errors in parentheses. We find no evidence suggesting that observably weaker candidates are more likely to attend the fairs: education, gender, and current employment do not significantly predict attendance. The only two robust predictors of attendance are instead associated with a positive motivation to work: attendance is higher among those job-seekers who search the most at baseline and who produce a formal certificate to employers.

Appendix Table B.9: **Main industry classifications**

Main Industry	Frequency	Percent
Tours-Hospitality	92	18.7
Finance, Services, Retail	102	20.7
Education, Health, Aid	104	21.1
Manufacturing	126	25.6
Construction, Mining, Farming	69	14.0
Total	493	100

Note: This table shows the initial partitioning of firms into five main industries prior to randomisation.

Appendix Table B.10: **Blocking variables for the firm randomisation**

VARIABLE	DEFINITION	SOURCE (QUESTION NUMBER)
plc	Firm is a private limited company	$g3 = 3$
total.n.all	Total number of pay-roll employees at the firm	$l1_1.n$
prop.p	Proportion of workers who are professionals	$l1_5.n/l1_1.n$
ed.deg	Number of workers at the firm with a degree	$rowtotal(l1_19_1)/rowtotal(ed_total) *$
to.all	Rate of turnover in the last year	$rowtotal(l2_1_*)/total.n.all$
formal.adv	Firms advertise when recruiting for jobs	$l4_2_1=1$ or $l4_2_2=1$
fairs	Firms expressed interest in attending a job fair	$l4_31$
hire.all	Rate of new hiring in the last year	$rowtotal(l3_2_*)/total.n.all$

Note: This table defines the variables used for blocking for firm randomisation.

Constant	0.834***	1.051**	1.302	0.835
	(0.128)	(0.411)	(0.987)	(1.465)
Observations	232	70	87	61
R-squared	0.075	0.075	0.102	0.576

Note: This table reports results from a series of Linear Probability Models; in each case, the outcome variable is a dummy for whether a firm attended the job fairs, conditional upon having been invited. Parentheses show heteroskedasticity-robust standard errors. The omitted industry dummy is for 'construction/mining'.

Appendix Table B.12: **Determinants of attrition among job-seekers**

Fairs	-0.025** (0.012)	Oromo	-0.007 (0.016)
Work frequency (weeks of 2 months)	0.007 (0.018)	Wage empl (6m)	0.017 (0.014)
Degree	-0.024 (0.017)	Married	-0.015 (0.017)
Worked (7d)	-0.015 (0.016)	Years since school	0.000 (0.0027)
Searched job (7d)	0.008 (0.014)	Lives with parents	0.008 (0.015)
Female	0.029** (0.013)	Ever had permanent job	0.002 (0.019)
Respondent age	0.000 (0.0027)	Searched job (6m)	-0.020 (0.017)
Born outside Addis	0.031** (0.015)	Amhara	0.000 (0.014)
		Constant	0.061 (0.060)
Average Attrition	6.7%		
Observations	1,827	R-squared	0.012
F-test (covariates)	1.130	F-test (treatment)	4.320
<i>p</i> -value (covariates)	0.320	<i>p</i> -value (treatment)	0.038

Note: This table reports regression results from a Linear Probability Model, in which the dependent variable is a dummy for whether a job-seeker attrited between baseline and endline; parentheses show heteroskedasticity-robust standard errors.

Appendix Table B.13: **Firm recruitment in the last year**

<i>Outcome</i>	Estimated ITT	Control Mean	Obs.
<i>Panel A: Short term recruitment outcomes</i>			
Time taken to fill professional vacancies	-2.344 (1.986) [.658]	24.11	338
Time taken to fill non-professional vacancies	0.724 (1.751) [.909]	15.66	109
Number of interviews per position (professional)	0.312 (2.355) [.909]	8.818	361
Pay per recruitment (professional)	746.7 (1030.791) [.909]	2818	382
Pay per recruitment (non-professional)	-437.8 (320.543) [.658]	1259	406
Unfilled vacancies	0.601 (.247)** [.101]	0.859	305
<i>Panel B: Characteristics of workers recruited</i>			
Number of new hires for the year (professional)	-1.604 (2.688) [1]	11.73	472
Number of new hires for the year (non-professional)	-9.704 (7.283) [1]	44.64	472
Did firms mostly hire people with degrees (professional positions)?	-0.00800 (.041) [1]	0.574	473
Percentage of new hires hired in permanent positions (non-professional)	-0.00900 (.03) [1]	0.892	337
Percentage of new hires hired in permanent positions (professional)	-0.00800 (.031) [1]	0.876	308

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Table B.14: **Impacts on firm hiring after job fairs**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Number of vacancies	0.169 (.266) [1]	1.115	422
New Hires	-0.671 (.866) [1]	3.907	422
Hiring shortfall	-0.0160 (.034) [1]	0.0290	193
Unfilled vacancies	0.380 (.785) [1]	2.143	422

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.15: **Impacts on firm hire quality after job fairs**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Permanent workers hired	0.0200 (.049) [1]	0.336	422
Days taken to recruit for position (avg)	0.311 (1.386) [1]	11.75	190
Starting salary of new recruits (avg)	-673.9 (636.454) [1]	1031	160
Workers with degrees hired (%)	-0.0430 (.044) [1]	0.237	422

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q -values are reported in square brackets.

Appendix Table B.16: **Firms' total workforce composition**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Total number of employees	-18.38 (16.581) [.847]	350.5	473
Proportion of professional workers on permanent contracts	0.0190 (.019) [.847]	0.908	462
Proportion of non-professional workers on permanent contracts	0.0280 (.02) [.67]	0.896	408
Average starting salary (professional)	-53.52 (235.925) [1]	4280	454
Average starting salary (non-professional)	102.9 (126.66) [.847]	1059	400
Proportion of professional workers with degree	-0.0570 (.027)** [.366]	0.645	461
Proportion of workers with post-secondary education (non-professionals)	0.0370 (.027) [.67]	0.355	407
Average worker is not under-qualified in any of the worker categories	0.00300 (.038) [1]	0.752	473

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.17: **Impacts on firm turnover and employee growth**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firing rate (professionals)	0.00400 (.004) [1]	0.00600	458
Firing rate (non-professionals)	0.00300 (.005) [1]	0.0130	319
Quit rate (professionals)	0.00800 (.02) [1]	0.143	458
Quit rate (non-professionals)	0.0250 (.037) [1]	0.134	320
Employee growth rate	0.0170 (.016) [1]	0.0140	472
Employee growth rate (professionals)	-0.0140 (.03) [1]	0.0310	467

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.18: **Impacts on firm human resources policies and attitudes**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firm reports HR problem	0.0820 (.037)** [.217]	0.752	473
Uses incentives in HR	0.0390 (.043) [.588]	0.595	473
Firm estimate of a fair wage	201.2 (312.897) [.592]	5463	452
Uses short term contractors	0.0480 (.045) [.588]	0.479	473
Uses performance rewards (professionals)	-0.0300 (.045) [.592]	0.545	473
Uses performance rewards (non-professionals)	-0.0740 (.045)* [.417]	0.562	473
Retrains poor performers	0.0390 (.04) [.588]	0.719	473

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Figure B.1: Attrition rate from the Phone Survey by Month

Notes: This figure shows the trajectory of monthly attrition rates over the course of the phone survey. Attrition is defined as failure to complete one interview.

Appendix Table B.19: **Impacts on firm growth and productivity**

<i>Outcome</i>	Estimated ITT	Control Mean	Observations
Firm is for-profit	-0.0140 (.011) [1]	0.867	471
Sales Revenue (last year)	-17575 (23388.044) [1]	144370	331
Value Added	-15491 (11969.701) [1]	80851	327
Profit (inferred)	6026 (4791.574) [1]	12975	326
Self-reported profit	1853 (7175.053) [1]	29626	313
Capital stock	60034 (123774.721) [1]	185398	279
Investment (12 months)	-6452 (5920.8) [1]	20147	398
Sales per worker	-57.12 (76.278) [1]	604.5	330
Value added per worker	19.45 (28.102) [1]	220.3	326

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets.

Appendix Table B.20: **Firms' reasons for not hiring workers they met at the fairs**

Main self-reported reason	Percent
Insufficient work experience	34.38
Wrong expertise	7.03
Wrong educational qualifications	23.44
Poor performance at the interview	7.03
The candidates we wanted were hired by other firms	3.91
Poor references	2.34
Salary disagreement	2.42
Workers were not interested or did not apply	1.61
Workers arrived late	1.61
Firm did not have vacancies at the time of the fair	3.23
Other	10.48

Appendix Table B.21: **Dyadic regressions: Firm requests to meet workers as function of worker characteristics**

	(1)	(2)	(3)	(4)
	Firm requested to meet worker			
Worker has some permanent work experience	0.0173*** (0.00657)		0.0151** (0.00652)	0.0132** (0.00617)
Worker is recent graduate	0.00185 (0.00379)	0.00185 (0.00379)	-0.000304 (0.00450)	0.00153 (0.00479)
Worker has certificate with application	0.00190 (0.00273)	0.00190 (0.00273)	0.00136 (0.00285)	0.00182 (0.00286)
Worker has postsecondary education	0.00729*** (0.00257)	0.00729*** (0.00257)	0.00783*** (0.00270)	0.00808*** (0.00279)
Permanent work experience * fresh graduate	-0.00610 (0.00948)	-0.00610 (0.00948)	-0.00317 (0.01000)	-0.000833 (0.0107)
Permanent work experience * Highschool only	-0.0180*** (0.00663)	-0.000785 (0.00421)	-0.0162** (0.00679)	-0.0139** (0.00652)

GS- algorithm suggested match			0.0256*** (0.00805)	0.0266*** (0.00833)
GS- matches we randomly suggested			-0.000233 (0.00792)	-0.00527 (0.00661)
Controls: Firms' vacancy characteristics	No	No	Yes	Yes
Controls: Firm baselien characteristics	No	No	No	Yes
Observations	19,110	19,110	18,185	17,491
R-squared	0.003	0.003	0.005	0.007

Notes: We regress on worker-firm dyadic data for all workers and firms who were invited to the same job fair, whether the firm requested to meet that worker in person, using a centralized meeting-request system facilitated at the job fairs. We include controls for worker characteristics, firm characteristics, and vacancy characteristics (vacancies held by the firm in question at the time of the job fairs).

Appendix Table B.22: Heterogeneous effects: firm recruitment by baseline proportion of youth in workforce

	(1)	(2)	(3)	(4)	(5)
	Firm performed formal interviews (professionals)	Firm performed formal interviews (non-professionals)	Did any advertising for new hires	Did advertising for professional positions	Did advertising on the job boards

Standard errors in parentheses
*** p<0.01, ** p<0.05, * p<0.1

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses; False Discovery Rate q-values are reported in square brackets, corrected for the tests conducted within each panel.

Appendix Figure B.2: Distribution of employer beliefs by education

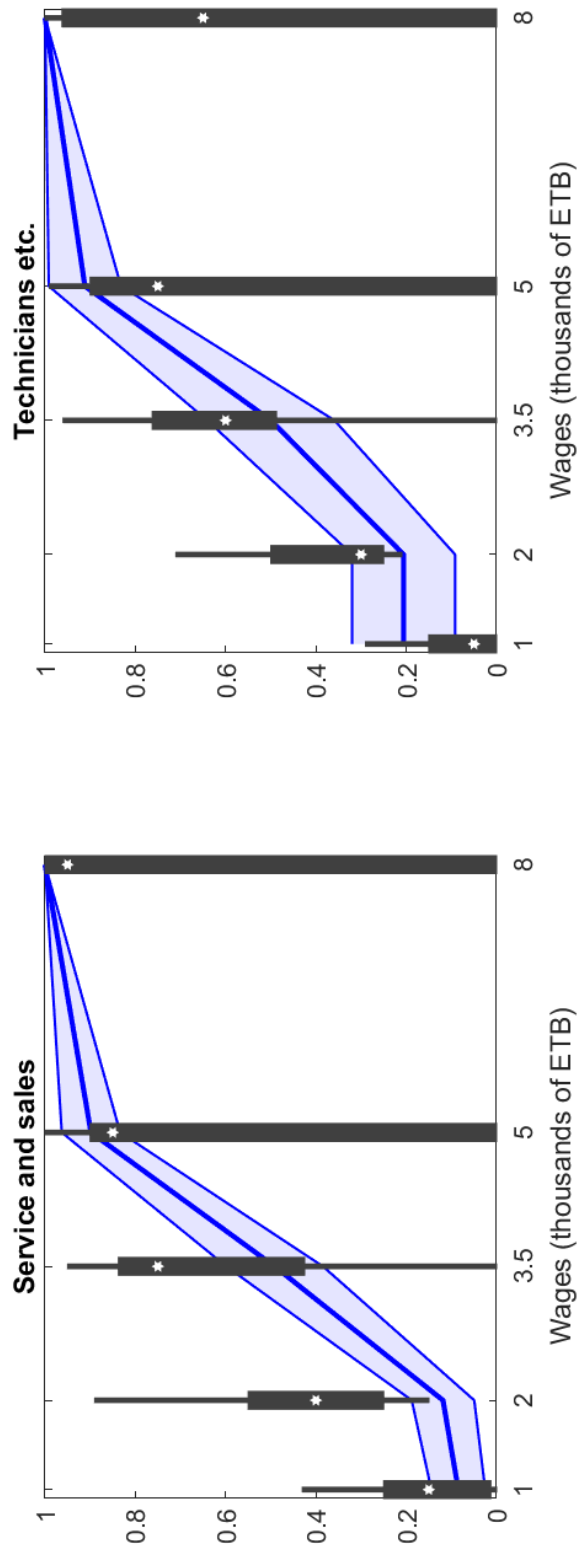

Notes: Each panel shows the distribution of employer beliefs, for some specific job-seeker characteristic. Each panel shows a kernel density plot (with bandwidth chosen using Silverman's plug-in), then a box-plot (showing 5th, 25th, 50th, 75th and 95th percentiles), followed by a direct visualisation of data (with random vertical jitter). For each panel, we superimpose a vertical line at the true value of the statistic in our sample.

Appendix Figure B.3: Firms' beliefs about the distribution of job-seekers' reservation wages: Secondary-educated job-seekers

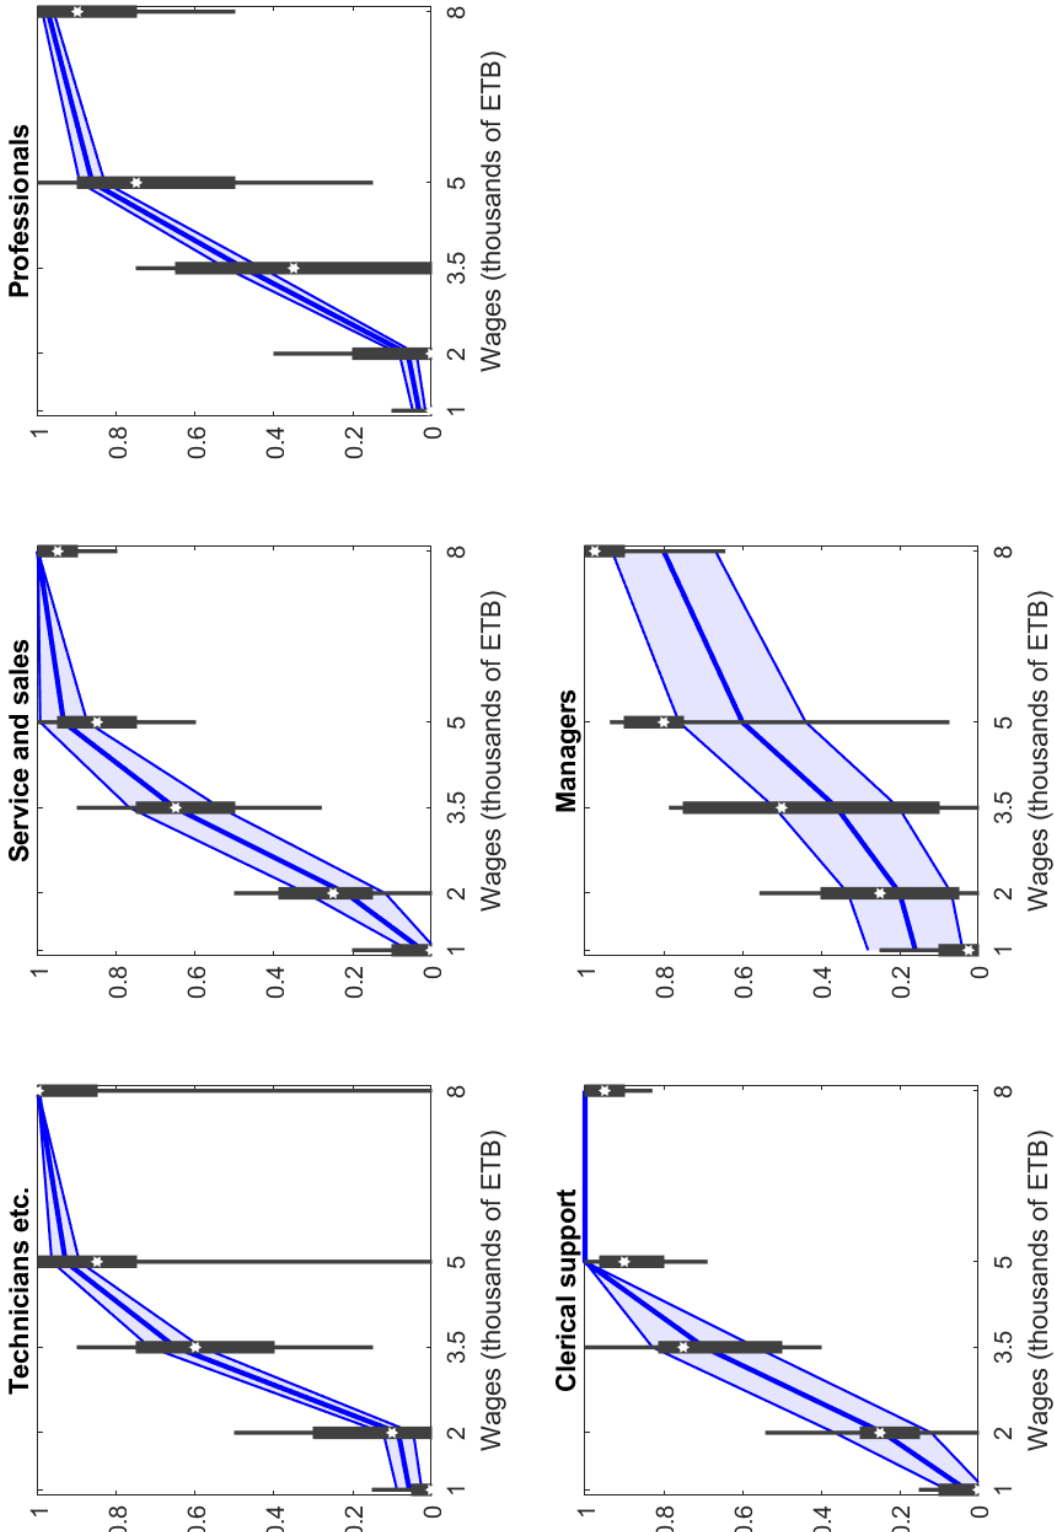

Notes: These figures show the distribution of firm beliefs about job-seekers' reservation wages. In each graph, we show this at five wage points: in each case, we show the distribution of firm beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our job-seekers with a given reservation wage (where the shaded area represents the 90% confidence interval for the proportion).

Appendix Figure B.4: Job-seekers' beliefs about the distribution of firm wages: Secondary-educated job-seekers

Notes: These figures show the distribution of job-seeker beliefs about firms' wages. In each graph, we show this at five wage points: in each case, we show the distribution of job-seeker beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our firms with a given wage (where the shaded area represents the 90% confidence interval for the proportion).

Appendix Figure B.5: Job-seekers' beliefs about the distribution of firm wages: Tertiary-educated job-seekers

Notes: These figures show the distribution of job-seeker beliefs about firms' wages. In each graph, we show this at five wage points: in each case, we show the distribution of job-seeker beliefs (using thin bars to show the 10th and 90th percentiles, thick bars to show the 25th and 75th percentiles, and a star symbol to show the median). The coloured lines show the true proportion of our firms with a given wage (where the shaded area represents the 90% confidence interval for the proportion).

Formal job		0.147 [0.137]	0.184 [0.140]			0.017 [0.122]	0.039 [0.123]	
Earnings		0.000 [0.000]	0.000 [0.000]			0.000 [0.000]	0.000 [0.000]	
Job satisfaction		0.028 [0.117]	0.072 [0.119]			0.186 [0.176]	0.232 [0.171]	
Job search at baseline (boards)			0.816 [0.121]***	0.771 [0.106]***			0.675 [0.133]***	0.676 [0.124]***
Constant	8.232 [4.446]*	12.271 [7.706]	13.070 [7.759]*	8.496 [4.414]*	0.224 [0.138]	0.193 [0.121]	0.072 [0.134]	0.117 [0.148]
First-stage F	11.825	5.565	5.545	11.861	13.411	8.475	8.689	13.676

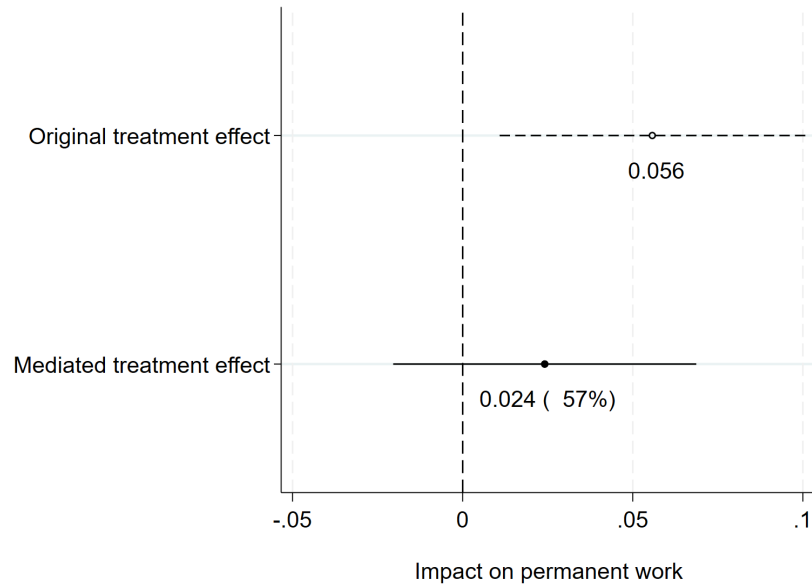

Notes: This table reports IV estimates of the impacts of endline beliefs (proxied by either reservation wages or the mismatch between reservation wages and market wages) on endline job search (measured by the number of visits respondents completed at the job boards). Beliefs are instrumented by the number of weeks it took respondents to find their first job after the baseline interview. The sample is thus restricted to individuals that were employed at least once during the study period. The last row of the table reports the first-stage F-statistic on the excluded instrument.

Appendix Table B.28: Impacts on search effectiveness for lower educated job seekers.

	(1)	(2)	(3)	(4)	(5)	(6)
	Interviews/Applications	Offers/Applications	Prepped CV	Used CV	Target manual lab	Target office job
Fairs	0.00191 (0.0459)	0.0499 (0.0580)	0.0238 (0.0413)	0.0238 (0.0413)	-0.00885 (0.0272)	0.0113 (0.0213)
Observations	263	262	545	545	545	545
R-squared	0.000	0.004	0.001	0.001	0.000	0.001
Control Mean	0.337	0.263	0.192	0.192	0.0958	0.0458

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses. The sample is restricted to job seekers who only completed high school. In column 5 the dependent variable is whether the respondent named as the primary focus of his/her search a job involving manual labor. Similarly, in column 6 the dependent variable is whether the respondent named as the primary focus of his/her search a job involving office work.

Appendix Figure B.8: **Mediation analysis of the effect on permanent employment using beliefs**

Note: This Figure reports (i) the treatment effect of the job fair intervention on permanent work for low-education jobseekers, and (ii) the Average Controlled Direct Effect (ACDE) of the job fair intervention on permanent work for low-education jobseekers holding the variable “wage mismatch” fixed. Next to the ACDE coefficient, we report the percent drop in the estimated treatment effect when wage mismatch is not allowed to change in response to treatment. This drop intuitively captures the share of the overall treatment effect on permanent work attributable to this mediator. We estimate the ACDE using the techniques described in Acharya et al. (2016).

Appendix Table B.29: **Effects of the fairs of sharing of information in job search networks**

	<i>Count within cluster</i>			All
	Known (1)	Given info (2)	Given recieved (3)	Num. Shared (4)
<i>Panel A: Average Treatment Effect</i>				
Fairs	0.418 (0.307)	0.062 (0.107)	0.071 (0.107)	-0.285 (0.430)
Observations	1,702	1,702	1,702	1,702
R-squared	0.144	0.073	0.073	0.042
Control Mean	2.000	0.470	0.454	5.242
Control SD	2.565	0.953	0.932	5.397
<i>Panel B: Treatment Effect by Education</i>				
Fairs*HighSchool	0.555 (0.355)	0.050 (0.132)	0.068 (0.132)	-0.285 (0.544)
Fairs*PostSecondary	0.193 (0.308)	0.081 (0.104)	0.075 (0.104)	-0.327 (0.480)
Observations	1,682	1,702	1,702	1,682
R-squared	0.145	0.073	0.073	0.043
ControlMean HighSchool	1.850	0.529	0.500	5.033
ControlMean PostSecond	2.070	0.442	0.432	5.339
ControlSD HighSchool	2.419	1.062	1.023	5.167
ControlSD PostSecond	2.629	0.898	0.886	5.503
Test High=Post (p)	0.200	0.794	0.954	0.941

Notes: Each row reports a separate regression. For each regression, we report the estimated ITT from participating in the job fair, the mean in the control group, and the number of observations. Standard errors are reported in parentheses. Column 1 shows the number of other individuals in our sample, in the sample cluster, that the individual knows. Column 2 shows the corresponding number that the individual has given information about a job to, and column 3 shows the number that the individual has received information about a job from. Column 4 shows that total number of people (not just within the sample and cluster) that the individual has shared job information with. The reference period for all questions is 30 days.
